Changelog

Changes from RO

- Changed title to reflect design changes.
- Renamed the proposed type from *basic_string_view* to *basic_string_span* following feedback from LEWG at the Kona meeting.
- Changed *basic_string_span* from a type alias for *span* to be a template class of its own, in order to be able to specify additional, string-specific construction and comparison behaviors.
- Added suggested overload for to_string().
- Separated out convenience type aliases for fixed- and dynamic- size string spans.

Introduction

This paper presents a design for *basic_string_span* (similar to the *basic_string_view* proposed in N3762 [1]) that would have an interface consistent with the *span* type described in P0122 [2]. Doing so improves the generality of the *basic_string_span* type and allows it to offer bounds-safety guarantees like *span*.

It is worth noting that the *basic_string_span* type presented here largely matches the interface of the *span* type proposed in P0122 [2].

Motivation and Scope

basic_string_span is a "vocabulary type" that is proposed for inclusion in the standard library. It can be widely used in C++ programs, as a replacement for passing const *basic_string* objects or zero-terminated character arrays. The *basic_string_span* design supports high performance and bounds-safe access to contiguous sequences of characters. This type would also improve modularity, composability, and reuse by decoupling accesses to string data from the specific container types used to store that data.

It is desirable that the interface offered by *basic_string_span* is harmonized with *span*, given the similarity between the purposes and functionality of the two types. This has the positive benefit of also reducing the number of interfaces that need to be learned by C++ programmers who want to perform bounds-safe, high-performance access to sequences – whether they are sequences of characters, or objects.

basic_string_span is presented as complementary type to the *basic_string_view* of N3762 [1]. Each fulfills an important but different aim. *basic_string_view* focuses on compatibility with the interface of *basic_string* and support for null-termination. *basic_string_span* is explicitly not null-terminated, and provides a simpler interface that is closer to a "view over a sequence of characters" model.

Impact on the Standard

basic_string_span is a pure library extension. It does not require any changes or extensions to the core language.

As described in the Design Decisions section, it would be convenient to overload *to_string()* for *basic_string_span* parameters.

basic_string_span as presented here has been implemented in standard C++ and successfully used within a commercial static analysis tool for C++ as well as commercial office productivity software. An open source reference implementation is available at https://github.com/Microsoft/GSL[3].

Design Decisions

Interface and naming similarity to span

The concept of a string is essentially a contiguous sequence of characters. A *span* is a vocabulary type that encapsulates access to a contiguous sequence of objects. A *basic_string_span* is a vocabulary type that encapsulates access to a contiguous sequence of characters. It is clear that at least conceptually (even if not necessarily in implementation) *basic_string_span* and *span* are related types.

In order to allow code that deals with contiguous sequences to look and behave uniformly (whether they are of characters or some other element type), *basic_string_span* consciously copies the interface of *span* (with some minor changes to construction and comparison). This design decision reduces the "surface area" that a C++ programmer must learn and remember to use each of these vocabulary types.

This, in turn, makes the requirement on string containers that *basic_string_span* can be a view over as simple as possible. The proposed form of *basic_string_span* can be used over a wide variety of string containers - such as *CString, const char*, BSTR, QString* or any of the other myriad of string types that are commonly used in C++ today. That capacity – to decouple functions from the details of the string type being used – is a significant benefit that *basic_string_span* can bring to C++ programmers.

Removing string-specific member functions

String-specific member functions (such as the overloads of *find()* on *basic_string*) are not offered on *basic_string_span*. This design decision follows the general approach of the standard library, which is to separate algorithms such as *find_first()* from the containers or views they operate over, by making them free functions. The lack of these string-specific member functions also makes it clearer to users of *string_view* objects that they cannot assume they are operating over a *basic_string.basic_string_span* is a type that should decouple users from the details of underlying string container types.

Zero termination

Historical conventions around zero-terminating the sequence of characters that form a string reflect implementation choices, rather than a fundamental aspect of the string concept. *basic_string_span* is completely agnostic of zero-termination requirements/promises in the string data it contains. This allows the view to be broadly adopted, as it can view over character sequences that are not zero-terminated, as well as those that happen to be.

basic_string_span does correctly initialize from string zero-terminated string constants (dropping the terminating zero from the view of the constructed *basic_string_span* object), for the sake of convenience.

Value Type Semantics

basic_string_span is designed as a value type – it is expected to be cheap to construct, copy, move, and use. Users are encouraged to use it as a pass-by-value parameter type wherever they would have passed a pointer to character by value or *basic_string* by reference.

Conceptually, *basic_string_span* is simply a pointer to some storage and a count of the elements accessible via that pointer. Those two values within a span can only be set via construction or assignment (i.e. all member functions other than constructors and assignment operators are *const*). This property makes it easy for users to reason about the values of a span through the course of a function body.

These value type characteristics also help provide compiler implementations with considerable scope for optimizing the use of *basic_string_span* within programs. For example, *basic_string_span* has a trivial destructor, so common ABI conventions allow it to be passed in registers.

Character traits

Although this proposal does not include character traits support in the proposed definition of *basic_string_span*, it is not prejudiced against such inclusion. It would certainly be possible to add an additional template parameter to the type alias if free functions that wanted to operate over *basic_string_span* would find a character traits template type argument helpful.

Static or dynamic length

basic_string_span objects are capable of being declared as either having a static-size (fixed at compiletime) or dynamic-size (provided at runtime). Conversions between the two varieties are allowed with limitations to ensure bounds-safety is always preserved. These conversions follow the same rules as for *span*. Fixed-size *basic_string_span* can be implemented with no size overhead when compared to passing a single pointer.

Mutable or const elements

basic_string_span as a type-alias can also support either read-only or mutable access to a sequence. To access read-only data, the user can declare a *basic_string_span<const char>* (for example), and access to mutable data would use a *basic_string_span<char>*. While it is acknowledged that the majority of *basic_string_span* usage would tend to be for read-only access, there are still uses for mutable access to an existing string. As an example, some programs deal with fixed-size strings for storage or communication protocols, and find it convenient to pass such a fixed-size string to functions that set or modify the elements prior to transmission or serialization.

Range-checking and bounds-safety

All accesses to the data encapsulated by a *basic_string_span* are conceptually range-checked to ensure they remain within the bounds of the *basic_string_span*. What actually happens as the result of a failure to meet *basic_string_span*'s bounds-safety constraints at runtime is undefined behavior. However, it should be considered effectively fatal to a program's ability to continue reliable execution. This is a critical aspect of *basic_string_span*'s design, and allows users to rely on the guarantee that as long as a sequence is accessed via a correctly initialized *basic_string_span*, then its bounds cannot be overrun.

As an example, in the current reference implementation, violating a range-check results by default in a call to *terminate()* but can also be configured via build-time mechanisms to continue execution (albeit with undefined behavior from that point on).

Conversion between fixed-size and dynamic-size *basic_string_span* objects is allowed, but with strict constraints that ensure bounds-safety is always preserved. At least two of these cases can be checked

statically by leveraging the type system. In each case, the following rules assume the element types of the *basic_string_span* objects are compatible for assignment.

- 1. A fixed-size *basic_string_span* may be constructed or assigned from another fixed-size *basic_string_span* of equal length.
- 2. A dynamic-size *basic_string_span* may always be constructed or assigned from a fixed-size *basic_string_span*.
- 3. A fixed-size *basic_string_span* may always be constructed or assigned from a dynamic-size *basic_string_span*. Undefined behavior will result if the construction or assignment is not bounds-safe. In the reference implementation, for example, this is achieved via a runtime check that results in *terminate()* on failure.

Construction

Construction is one place where *basic_string_span* differs from its "relative" *span*.

To simplify use of *basic_string_pan* as a simple parameter, *basic_string_span* offers a number of constructors for common string container types that store contiguous sequences of elements. As *basic_string_span* does not zero-terminate string data, it does a little extra work in some cases to avoid inadvertently including a terminator.

Most of the constructors for *basic_string_span* are equivalent to the constructors for span. However, the key differences are in the following summarized extract from the specification:

```
template <size_t N>
  constexpr basic_string_span(element_type(&arr)[N]);
template <size_t N>
  constexpr basic_string_span(array<remove_const_t<element_type>, N>& arr);
template <size_t N>
  constexpr basic_string_span(const array<remove_const_t<element_type>, N>& arr);
arr);
```

These three constructors check for a terminating zero in the characer sequence provided as input. If one is found, then it is not included in the *basic_string_span* being constructed. This allows code such as the following to behave in a least-surprise fashion:

```
// ss.size() returns 5. It has been constructed without the terminating '\0'
basic_string_span<const char, dynamic_extent> ss = "Hello";
```

There are also specific constructors that take *basic_string*, for convenience.

Convenience aliases

There are a number of "convenience" aliases provided for the various combinations of character types, *const*-ness, fixed- and dynamic-size that are commonly useful with *basic_string_span*:

```
using string_span = basic_string_span<char, dynamic_extent>;
using cstring_span = basic_string_span<const char, dynamic_extent>;
using wstring_span = basic_string_span<wchar_t, dynamic_extent>;
using cwstring_span = basic_string_span<const wchar_t, dynamic_extent>;
template<ptrdiff_t Extent>
using fixed_string_span = basic_string_span<char, Extent>;
template<ptrdiff_t Extent>
using fixed_cstring_span = basic_string_span<const char, Extent>;
template<size_t Extent>
using fixed_wstring_span = basic_string_span<wchar_t, Extent>;
template<size_t Extent>
using fixed_wstring_span = basic_string_span<wchar_t, Extent>;
```

to_string conversion

In usage, it is often convenient to take a *basic_string_span* parameter, but then wish to copy the sequence it views into a new *basic_string* container for further processing and storage. To support this scenario, it is proposed to overload the existing *to_string()* free function in the standard library so that it will construct a *basic_string* from a *basic_string_span*.

```
template<class CharT, ptrdiff_t Extent>
    basic_string<remove_const_t<CharT>> to_string(basic_string_span<CharT,
Extent> s);
```

Proposed Wording Changes

The following proposed wording changes against the working draft of the standard are relative to N4567 [4].

In these changes,

Yellow highlight is used to indicate modified text or sections.

Red highlight is used to indicate deleted text.

Green highlight is used to indicate newly added text.

17.6.1.2 Headers [headers]

2 The C++ standard library provides $\frac{54}{54}$ C++ library headers, as shown in Table 14.

```

23.7.2 Class template basic_string_span [basic_string_span]

1 A basic_string_span is a view over a contiguous sequence of characters, the storage of which is owned by some other object.

2 CharT is required to be either a narrow character type (3.9.1/1) or wchar t (3.9.1/5).

2 Throughout this section, whenever a requirement fails to be met, the result is considered undefined behavior. It may – for example – cause immediate termination via a call to terminate(), or cause an exception to be thrown.

3 The iterators for basic string span are all random access iterators and contiguous iterators.

4 For a basic_string_span<const T>, the iterator and const_iterator types are allowed to be synonyms.

basic_string<remove_const_t<CharT>> to_string(basic_string_span<CharT, Extent> s);

} // namespace std

23.7.2.1 basic_string_span constructors, copy, assignment, and destructor
[basic_string_span.cons]

constexpr basic_string_span(); constexpr basic string span(nullptr t);

Requires: extent == dynamic extent || extent == 0

Effects: Constructs an empty basic_string_span.

Postconditions: size() == 0 && data() == nullptr

Complexity: Constant.

constexpr basic_string_span(pointer s);

Requires: char traits<CharT>::length(s) <= PTRDIFF MAX</pre>

Returns: basic string(s, char traits<CharT>::length(s))

Complexity: Linear.

constexpr basic_string_span(pointer ptr, index_type count);

Requires: When ptr is null pointer then count shall be 0. When ptr is not null pointer, then it shall point to the beginning of a valid sequence of objects of at least count length. count shall always be >= 0. If extent is not dynamic extent, then count shall be equal to extent.

Effects: Constructs a basic_string_span that is a view over the sequence of objects pointed to by ptr. If ptr is null pointer or count is 0 then an empty basic_string_span is constructed.

Postconditions: size() == count && data() == ptr

Complexity: Constant.

constexpr basic_string_span(pointer firstElem, pointer lastElem);

Requires: [firstElem, lastElem) is a valid range and distance(firstElem, lastElem) >= 0.
If extent is not equal to dynamic_extent, then distance(firstElem, lastElem) shall be equal
to extent.

Effects: Constructs a basic_string_span that is a view over the range [firstElem, lastElem). If distance (firstElem, lastElem) then an empty span is constructed.

Postconditions: size() == distance(first, last) && data() == firstElem

Complexity: The same as for distance(first, last)

```
template <size_t N>
    constexpr basic_string_span(element_type (&arr)[N]);
    template <size_t N>
        constexpr basic_string_span(array<remove_const_t<element_type>, N>&
    arr);
    template <size_t N>
        constexpr basic_string_span(const_array<remove_const_t<element_type>, N>&
        N>& arr);
    N>& arr);
```

Requires: Unless extent == dynamic_extent, then either a trailing element with value
element_type{} shall be found and the count of elements up to and excluding that element shall
equal extent, or there shall be no trailing element with value element type{} and N == extent.

Effects: Constructs a **basic_string_span** that is a view over the supplied array, excluding any zero-termination that may exist.

Complexity: Linear in the size of arr.

template <class Container>
 constexpr basic_string_span(Container& cont);

Requires: The constructor shall not participate in overload resolution unless:

Container meets the requirements of both a contiguous container (defined in 23.2.1/13) and a sequence container (defined in 23.2.3).

The Container implements the optional sequence container requirement of operator[] (defined in Table 100).

Container::value_type is the same as remove_const_t<element_type>.

The constructor shall not participate in overload resolution if Container is a basic_string_span or array or basic_string.

If extent is not equal to dynamic_extent, then cont.size() shall be equal to extent.

Effects: Constructs a basic_string_span that is a view over the sequence owned by cont.

Postconditions: size() == cont.size() && data() == addressof(cont[0])

Complexity: Constant.

template <class Container>
 basic string span(const Container&&) = delete;

Requires: The constructor shall not participate in overload resolution unless:

Container meets the requirements of both a contiguous container (defined in 23.2.1/13) and a sequence container (defined in 23.2.3).

The Container implements the optional sequence container requirement of operator[] (defined in Table 100).

Container::value_type is the same as remove_const_t<element_type>.

The constructor shall not participate in overload resolution if Container is a basic_string_span or array or basic_string.

constexpr basic_string_span(const basic_string_span& other) noexcept =
default;

constexpr basic_string_span(basic_string_span&& other) noexcept =
default;

Effects: Constructs a basic_string_span by copying the implementation data members of another basic_string_span.

Postconditions: other.size() == size() && other.data() == data()

Complexity: Constant.

Requires: These constructors shall not participate in overload resolution unless OtherCharT differs from CharT only by cv-qualifiers. If extent is not equal to dynamic_extent, then other.size() shall be equal to extent.

Effects: Constructs a basic_string_span by copying the implementation data members of another basic_string_span, performing suitable conversions.

Postconditions: size() == other.size() &&
data() == reinterpret_cast<pointer>(other.data())

Complexity: Constant.

Requires: If extent is not equal to dynamic extent, then s.length() shall be equal to extent.

Effects: Constructs a basic_string_span that is a view over the character sequence owned by the supplied basic_string.

Postconditions: size() == s.length() &&
data() == reinterpret cast<pointer>(addressof(s[0]))

Complexity: Constant.

basic_string_span& operator=(const basic_string_span& other) noexcept =
default;
basic_string_span& operator=(basic_string_span&& other) noexcept =
default;

Effects: Assigns the implementation data of one basic string span into another.

Postconditions: size() == other.size() && data() == other.data()

Complexity: Constant.

23.7.2.2 basic string span subviews [basic_string_span.sub]

Requires: Count >= 0 && Count <= size()

Effects: Returns a new basic_string_span that is a view over the initial Count elements of the current basic_string_span.

Returns: basic string span(data(), Count);

Complexity: Constant.

template <ptrdiff_t Count>
 constexpr basic string span<element type, Count> last() const;

Requires: Count >= 0 && Count <= size()

Effects: Returns a new <code>basic_string_span</code> that is a view over the final <code>Count</code> elements of the current <code>basic_string_span</code>.

Returns: basic_string_span(Count == 0 ? data() : data() + (size() - Count),
Count)

Complexity: Constant.

_template <ptrdiff_t Offset, ptrdiff_t Count = dynamic_extent>_____ constexpr basic_string_span<element_type, Count> subspan() const;

Requires: (Offset == 0 || Offset > 0 && Offset < size()) && (Count == dynamic extent || Count >= 0 && Offset + Count <= size())

Effects: Returns a new basic_string_span that is a view over Count elements of the current basic_string_span starting at element Offset. If Count is equal to dynamic_extent, then a basic string span over all elements from Offset onwards is returned.

Returns: basic_string_span(data() + Offset, Count == dynamic_extent ? size() Offset : Count)

Complexity: Constant

constexpr basic_string_span<element_type, dynamic_extent>
first(index type count) const;

Requires: count >= 0 && count <= size()

Effects: Returns a new basic_string_span that is a view over the initial count elements of the current basic_string_span.

Returns: basic string span(data(), count);

Complexity: Constant.

constexpr basic_string_span<element_type, dynamic_extent>
last(index_type count) const;

Requires: Count >= 0 && Count <= size()

Effects: Returns a new basic_string_span that is a view over the final Count elements of the current basic_string_span.

Returns: basic_string_span(Count == 0 ? data() : data() + (size() - Count),
Count)

Complexity: Constant.

constexpr basic_string_span<element_type, dynamic_extent>
subview(index_type offset, index_type count = dynamic_extent) const;

Requires: (Offset == 0 || Offset > 0 && Offset < size()) && (Count == dynamic extent || Count >= 0 && Offset + Count <= size())

Effects: Returns a new basic_string_span that is a view over Count elements of the current basic_string_span starting at element Offset. If Count is equal to dynamic_extent, then a basic string span over all elements from Offset onwards is returned.

Returns: basic_string_span(data() + Offset, Count == dynamic_extent ? size() Offset : Count)

Complexity: Constant

23.7.2.2 basic_string_span observers [basic_string_span.obs]

constexpr index_type length() const noexcept;

Effects: Equivalent to size().

constexpr index type size() const noexcept;

Effects: Returns the number of elements accessible through the basic string span.

Returns: >= 0

Complexity: Constant

constexpr index_type length_bytes() const noexcept;

Effects: Equivalent to size_bytes().

constexpr index_type size_bytes() const noexcept;

Effects: Returns the number of bytes used for the object representation of all elements accessible through the basic string span.

Returns: size() * sizeof(element_type)

Complexity: Constant

constexpr bool empty() const noexcept;

Effects: Equivalent to size() == 0.

Returns: size() == 0

Complexity: Constant

23.7.2.3 basic string span element access [basic_string_span.elem]

constexpr reference operator[](index_type idx) const; constexpr reference operator()(index type idx) const;

Requires: idx >= 0 && idx < size()</pre>

Effects: Returns a reference to the element at position idx.

Returns: * (data() + idx)

Complexity: Constant

constexpr pointer data() const noexcept;

Effects: Returns either a pointer to the first element in the sequence accessible via the basic_string_span or the null pointer if that was the value used to construct the basic string span.

Returns: (for exposition) data

Complexity: Constant

23.7.2.4 basic_string_span iterator support [basic_string_span.iterators]

iterator begin() const noexcept; const iterator cbegin() const noexcept;

Returns: An iterator referring to the first element in the basic string span.

Complexity: Constant

iterator end() const noexcept; const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

Complexity: Constant

reverse_iterator rbegin() const noexcept; const reverse iterator crbegin() const noexcept;

Returns: An iterator that is semantically equivalent to reverse iterator (end()).

Complexity: Constant

reverse_iterator rend() const noexcept; const reverse iterator crend() const noexcept;

Returns: An iterator that is semantically equivalent to reverse iterator (begin ()).

Complexity: Constant

23.7.2.5 basic string span comparison operators [basic_string_span.comparison]

template <class CharT, ptrdiff_t Extent>
 constexpr bool operator==(const basic_string_span<CharT, Extent>& l,
const basic string span<CharT, Extent>& r) const noexcept;

Effects: Equivalent to equal(l.begin(), l.end(), r.begin(), r.end()).

template <class CharT, ptrdiff_t Extent>
 constexpr bool operator!=(const basic_string_span<CharT, Extent>& 1,
const basic string span<CharT, Extent>& r) const noexcept;

Effects: Equivalent to ! (1 == r).

cemplate <class CharT, ptrdiff_t Extent> constexpr bool operator<(const basic_string_span<CharT, Extent>& l, const basic_string_span<CharT, Extent>& r) const noexcept;

Effects: Equivalent to lexicographical_compare(l.begin(), l.end(), r.begin(), r.end()).

template <class CharT, ptrdiff_t Extent>

```
constexpr bool operator>(const basic_string_span<CharT, Extent>& l,
const basic_string_span<CharT, Extent>& r) const noexcept;
```

Effects: Equivalent to (r < 1).

```
template <class CharT, ptrdiff_t Extent>
    constexpr bool operator<=(const basic_string_span<CharT, Extent>& l,
    const basic_string_span<CharT, Extent>& r) const noexcept;
```

Effects: Equivalent to ! (1 > r).

```
template <class CharT, ptrdiff_t Extent>
    constexpr bool operator>=(const basic_string_span<CharT, Extent>& l,
    const basic_string_span<CharT, Extent>& r) const noexcept;
Effects: Equivalent to !(l < r).
23.7.2.6 basic string span to basic string conversion [basic_string_span.basic_string]
```

```
template<class CharT, ptrdiff_t Extent>
    basic_string<remove_const_t<CharT>> to_string(basic_string_span<CharT,
Extent> s);
```

Returns: basic string(s.data(), s.size())

Acknowledgements

basic_string_span was designed to support the C++ Core Coding Guidelines [5] and as such, the current version reflects the input of Herb Sutter, Jim Springfield, Gabriel Dos Reis, Chris Hawblitzel, Gor Nishanov, and Dave Sielaff. Łukasz Mendakiewicz, Bjarne Stroustrup, Eric Niebler and Artur Laksberg provided helpful review during development. Anna Gringauze provided many useful insights and design fixes and wrote an initial implementation.

Many thanks to Gabriel Dos Reis and Stephan T. Lavavej for their valuable input to this document.
