If the reserved word **!** does not precede the pipeline, the exit status shall be the exit status of the last command specified in the pipeline. Otherwise, the exit status shall be the logical NOT of the exit status of the last command. That is, if the last command returns zero, the exit status shall be 1; if the last command returns greater than zero, the exit status shall be zero.

2.9.3 Lists

An *AND-OR list* is a sequence of one or more pipelines separated by the operators "&&" and "||".

A *list* is a sequence of one or more AND-OR lists separated by the operators ';' and '&' and optionally terminated by ';', '&', or <newline>.

The operators "&&" and "||" shall have equal precedence and are evaluated from beginning to end. For example, both of the following commands write solely **bar** to standard output:

```
false && echo foo || echo bar
true || echo foo && echo bar
```

A ';' or <newline> character terminator shall cause the preceding AND-OR list to be executed sequentially; an '&' shall cause asynchronous execution of the preceding AND-OR list.

The term *compound-list* is derived from the grammar in Section 2.11 (on page 2266); it is equivalent to a sequence of *lists*, separated by <newline> characters, that can be preceded or followed by an arbitrary number of <newline> characters.

Examples

The following is an example that illustrates <newline> characters in compound-lists:

```
while
    # a couple of <newline>s

    # a list
    date && who || ls; cat file
    # a couple of <newline>s

    # another list
    wc file > output & true

do
    # 2 lists
    ls
    cat file
done
```

2.9.3.1 Asynchronous Lists

If a command is terminated by the control operator ampersand ('&'), the shell shall execute the command asynchronously in a subshell. This means that the shell shall not wait for the command to finish before executing the next command.

The format for running a command in the background is:

command1 & [*command2* & ...]

The standard input for an asynchronous list, before any explicit redirections are performed, shall be considered to be assigned to a file that has the same properties as **/dev/null**. If it is an interactive shell, this need not happen. In all cases, explicit redirection of standard input shall override this activity.

When an element of an asynchronous list (the portion of the list ended by an ampersand, such as *command1*, above) is started by the shell, the process ID of the last command in the asynchronous list element shall become known in the current shell execution environment; see Section 2.13 (on page 2273). This process ID shall remain known until:

1. The command terminates and the application waits for the process ID.
2. Another asynchronous list invoked before "$!" (corresponding to the previous asynchronous list) is expanded in the current execution environment.

The implementation need not retain more than the {CHILD_MAX} most recent entries in its list of known process IDs in the current shell execution environment.

Exit Status

The exit status of an asynchronous list shall be zero.

2.9.3.2 *Sequential Lists*

Commands that are separated by a semicolon (';') shall be executed sequentially.

The format for executing commands sequentially shall be:

command1 **[**; *command2***]** ...

Each command shall be expanded and executed in the order specified.

Exit Status

The exit status of a sequential list shall be the exit status of the last command in the list.

2.9.3.3 *AND Lists*

The control operator "&&" denotes an AND list. The format shall be:

command1 **[** && *command2***]** ...

First *command1* shall be executed. If its exit status is zero, *command2* shall be executed, and so on, until a command has a non-zero exit status or there are no more commands left to execute. The commands are expanded only if they are executed.

Exit Status

The exit status of an AND list shall be the exit status of the last command that is executed in the list.

2.9.3.4 *OR Lists*

The control operator "||" denotes an OR List. The format shall be:

command1 **[** || *command2***]** ...

First, *command1* shall be executed. If its exit status is non-zero, *command2* shall be executed, and so on, until a command has a zero exit status or there are no more commands left to execute.

Exit Status

The exit status of an OR list shall be the exit status of the last command that is executed in the list.

2.9.4 Compound Commands

The shell has several programming constructs that are *compound commands*, which provide control flow for commands. Each of these compound commands has a reserved word or control operator at the beginning, and a corresponding terminator reserved word or operator at the end. In addition, each can be followed by redirections on the same line as the terminator. Each redirection shall apply to all the commands within the compound command that do not explicitly override that redirection.

2.9.4.1 Grouping Commands

The format for grouping commands is as follows:

(*compound-list*) Execute *compound-list* in a subshell environment; see Section 2.13 (on page 2273). Variable assignments and built-in commands that affect the environment shall not remain in effect after the list finishes.

{ *compound-list*;} Execute *compound-list* in the current process environment. The semicolon shown here is an example of a control operator delimiting the **}** reserved word. Other delimiters are possible, as shown in Section 2.11 (on page 2266); a <newline> character is frequently used.

Exit Status

The exit status of a grouping command shall be the exit status of *list*.

2.9.4.2 For Loop

The **for** loop executes a sequence of commands for each member in a list of *items*. The **for** loop requires that the reserved words **do** and **done** be used to delimit the sequence of commands.

The format for the **for** loop is as follows:

```
for name [ in [word ... ]]
do
    compound-list
done
```

First, the list of words following **in** shall be expanded to generate a list of items. Then, the variable *name* shall be set to each item, in turn, and the *compound-list* executed each time. If no items result from the expansion, the *compound-list* shall not be executed. Omitting:

```
in word…
```

is equivalent to:

```
in "$@"
```

Exit Status

The exit status of a **for** command shall be the exit status of the last command that executes. If there are no items, the exit status shall be zero.

2046 *2.9.4.3 Case Conditional Construct*

2047 The conditional construct **case** shall execute the *compound-list* corresponding to the first one of
2048 several *patterns* (see Section 2.14 (on page 2274)) that is matched by the string resulting from the
2049 tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote
2050 removal of the given word. The reserved word **in** shall denote the beginning of the patterns to be
2051 matched. Multiple patterns with the same *compound-list* shall be delimited by the '|' symbol.
2052 The control operator ')' terminates a list of patterns corresponding to a given action. The
2053 *compound-list* for each list of patterns, with the possible exception of the last, shall be terminated
2054 with ";;". The **case** construct terminates with the reserved word **esac** (**case** reversed).

2055 The format for the **case** construct is as follows:

```
2056    case word in
2057        [(]pattern1) compound-list;;
2058        [[(]pattern[ | pattern] ... ) compound-list;;] ...
2059        [[(]pattern[ | pattern] ... ) compound-list]
2060    esac
```

2061 The ";;" is optional for the last *compound-list*.

2062 In order from the beginning to the end of the **case** statement, each *pattern* that labels a
2063 *compound-list* shall be subjected to tilde expansion, parameter expansion, command substitution,
2064 and arithmetic expansion, and the result of these expansions shall be compared against the
2065 expansion of *word*, according to the rules described in Section 2.14 (on page 2274) (which also
2066 describes the effect of quoting parts of the pattern). After the first match, no more patterns shall
2067 be expanded, and the *compound-list* shall be executed. The order of expansion and comparison of
2068 multiple *pattern*s that label a *compound-list* statement is unspecified.

2069 **Exit Status**

2070 The exit status of **case** shall be zero if no patterns are matched. Otherwise, the exit status shall be
2071 the exit status of the last command executed in the *compound-list*.

2072 *2.9.4.4 If Conditional Construct*

2073 The **if** command shall execute a *compound-list* and use its exit status to determine whether to
2074 execute another *compound-list*.

2075 The format for the **if** construct is as follows:

```
2076    if compound-list
2077    then
2078        compound-list
2079    [elif compound-list
2080    then
2081        compound-list] ...
2082    [else
2083        compound-list]
```

2084 The **if** *compound-list* shall be executed; if its exit status is zero, the **then** *compound-list* shall be
2085 executed and the command shall complete. Otherwise, each **elif** *compound-list* shall be executed,
2086 in turn, and if its exit status is zero, the **then** *compound-list* shall be executed and the command
2087 shall complete. Otherwise, the **else** *compound-list* shall be executed.

Exit Status

The exit status of the **if** command shall be the exit status of the **then** or **else** *compound-list* that was executed, or zero, if none was executed.

2.9.4.5 While Loop

The **while** loop shall continuously execute one *compound-list* as long as another *compound-list* has a zero exit status.

The format of the **while** loop is as follows:

```
while compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a non-zero exit status, the **while** command shall complete. Otherwise, the *compound-list-2* shall be executed, and the process shall repeat.

Exit Status

The exit status of the **while** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.4.6 Until Loop

The **until** loop shall continuously execute one *compound-list* as long as another *compound-list* has a non-zero exit status.

The format of the **until** loop is as follows:

```
until compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a zero exit status, the **until** command completes. Otherwise, the *compound-list-2* shall be executed, and the process repeats.

Exit Status

The exit status of the **until** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.5 Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a *function definition command*.

The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named *fname*; the application shall ensure that it is a name (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.232, Name). An implementation may allow other characters in a function name as an extension. The implementation shall maintain separate name spaces for functions and variables.

The argument *compound-command* represents a compound command, as described in Section 2.9.4 (on page 2261).

When the function is declared, none of the expansions in Section 2.6 (on page 2244) shall be performed on the text in *compound-command* or *io-redirect*; all expansions shall be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* shall be performed during the execution of the function itself, not the function definition. See Section 2.8.1 (on page 2255) for the consequences of failures of these operations on interactive and non-interactive shells.

When a function is executed, it shall have the syntax-error and variable-assignment properties described for special built-in utilities in the enumerated list at the beginning of Section 2.15 (on page 2276).

The *compound-command* shall be executed whenever the function name is specified as the name of a simple command (see Section 2.9.1.1 (on page 2257)). The operands to the command temporarily shall become the positional parameters during the execution of the *compound-command*; the special parameter '#' also shall be changed to reflect the number of operands. The special parameter 0 shall be unchanged. When the function completes, the values of the positional parameters and the special parameter '#' shall be restored to the values they had before the function was executed. If the special built-in *return* is executed in the *compound-command*, the function completes and execution shall resume with the next command after the function call.

Exit Status

The exit status of a function definition shall be zero if the function was declared successfully; otherwise, it shall be greater than zero. The exit status of a function invocation shall be the exit status of the last command executed by the function.

2.10 Executable Script

XSI XSI-Conformant systems shall support executable scripts. A successful call to a function of the *exec* family with an executable script as the first parameter shall result in a new process, where the process image that is started is that of the interpreter. The path name of the interpreter follows the "#!" characters.

If the executable script has a first line:

```
#! interpreter [arg]
```

then the interpreter shall be called with an argument array consisting of an unspecified zero'th argument, followed by *arg* (if present), followed by a path name for the script, followed by the arguments following the zero'th argument in the *exec* call of the script.

No shell operations (as described in Section 2.1 (on page 2235)) shall be performed on the first line of an executable script.

The behavior shall be unspecified if the first line of the executable script does not meet all of the following criteria:

1. The first line shall be in one of the formats below:

   ```
   "#!%s\n" interpreter
   "#!<delta>%s\n" interpreter
   "#!%s<delta>%s\n" interpreter arg
   "#!<delta>%s<delta>%s\n" interpreter arg
   ```

2. The *interpreter* argument shall be an absolute path name of an executable file other than an executable script.

3. The *interpreter* argument and the *arg* argument, if present, shall not contain any quoting characters.

4. The *interpreter* argument and the *arg* argument, if present, shall not contain any white-space characters.

5. The length of the first line shall be no longer than 80 bytes.

2.11 Shell Grammar

The following grammar defines the Shell Command Language. This formal syntax shall take precedence over the preceding text syntax description.

2.11.1 Shell Grammar Lexical Conventions

The input language to the shell must be first recognized at the character level. The resulting tokens shall be classified by their immediate context according to the following rules (applied in order). These rules are used to determine what a ‘‘token’’ is that is subject to parsing at the token level. The rules for token recognition in Section 2.3 (on page 2238) shall apply.

1. A <newline> character shall be returned as the token identifier **NEWLINE**.
2. If the token is an operator, the token identifier for that operator shall result.
3. If the string consists solely of digits and the delimiter character is one of `'<'` or `'>'`, the token identifier **IO_NUMBER** shall be returned.
4. Otherwise, the token identifier **TOKEN** results.

Further distinction on **TOKEN** is context-dependent. It may be that the same **TOKEN** yields **WORD**, a **NAME**, an **ASSIGNMENT**, or one of the reserved words below, dependent upon the context. Some of the productions in the grammar below are annotated with a rule number from the following list. When a **TOKEN** is seen where one of those annotated productions could be used to reduce the symbol, the applicable rule shall be applied to convert the token identifier type of the **TOKEN** to a token identifier acceptable at that point in the grammar. The reduction shall then proceed based upon the token identifier type yielded by the rule applied. When more than one rule applies, the highest numbered rule shall apply (which in turn may refer to another rule). (Note that except in rule 7, the presence of an `'='` in the token has no effect.)

The **WORD** tokens shall have the word expansion rules applied to them immediately before the associated command is executed, not at the time the command is parsed.

2.11.2 Shell Grammar Rules

1. [Command Name]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, the token **WORD** shall be returned. Also, if the parser is in any state where only a reserved word could be the next correct token, proceed as above. This rule applies rather narrowly: when a compound list is terminated by some clear delimiter (such as the closing **fi** of an inner **if_clause**) then it would apply; where the compound list might continue (as in after a `';'`), rule 7a (and consequently the first sentence of this rule) would apply. In many instances the two conditions are identical, but this part of this rule does not give license to treating a **WORD** as a reserved word unless it is in a place where a reserved word shall appear.

   Note: Because at this point quote marks are retained in the token, quoted strings cannot be recognized as reserved words. This rule also implies that reserved words are not recognized except in certain positions in the input, such as after a <newline> character or semicolon; the grammar presumes that if the reserved word is intended, it is properly delimited by the user, and does not attempt to reflect that requirement directly. Also note that line joining is done before tokenization, as described in Section 2.2.1 (on page 2236), so escaped <newline>s are already removed at this point.

Rule 1 is not directly referenced in the grammar, but is referred to by other rules, or applies globally.

2. [Redirection to or from file name]

   The expansions specified in Section 2.7 (on page 2251) shall occur. As specified there, exactly one field can result (or the result is unspecified), and there are additional requirements on path name expansion.

3. [Redirection from here-document]

   Quote removal shall be applied to the word to determine the delimiter that is used to find the end of the here-document that begins after the next <newline> character.

4. [Case statement termination]

   When the **TOKEN** is exactly the reserved word **esac**, the token identifier for **esac** shall result. Otherwise, the token **WORD** shall be returned.

5. [**NAME** in **for**]

   When the **TOKEN** meets the requirements for a name (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.232, Name), the token identifier **NAME** shall result. Otherwise, the token **WORD** shall be returned.

6. [Third word of **for** and **case**]

   When the **TOKEN** is exactly the reserved word **in**, the token identifier for **in** shall result. Otherwise, the token **WORD** shall be returned. (As indicated in the grammar, a *linebreak* precedes the token **in**. If <newline> characters are present at the indicated location, it is the token after them that is treated in this fashion.)

7. [Assignment preceding command name]

   a. [When the first word]

      If the **TOKEN** does not contain the character `'='`, rule 1 is applied. Otherwise, 7b shall be applied.

   b. [Not the first word]

      If the **TOKEN** contains the equal sign character:

      — If it begins with `'='`, the token **WORD** shall be returned.

      — If all the characters preceding `'='` form a valid name (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.232, Name), the token **ASSIGNMENT_WORD** shall be returned. (Quoted characters cannot participate in forming a valid name.)

      — Otherwise, it is unspecified whether it is **ASSIGNMENT_WORD** or **WORD** that is returned.

   Assignment to the **NAME** shall occur as specified in Section 2.9.1 (on page 2256).

8. [**NAME** in function]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, when the **TOKEN** meets the requirements for a name, the token identifier **NAME** shall result. Otherwise, rule 7 applies.

9. [Body of function]

Word expansion and assignment shall never occur, even when required by the rules above, when this rule is being parsed. Each **TOKEN** that might either be expanded or have assignment applied to it shall instead be returned as a single **WORD** consisting only of characters that are exactly the token described in Section 2.3 (on page 2238).

                 | newline_list
                 ;
```

2.12 Signals and Error Handling

When a command is in an asynchronous list, the shell shall prevent SIGQUIT and SIGINT signals from the keyboard from interrupting the command. Otherwise, signals shall have the values inherited by the shell from its parent (see also the *trap* (on page 2307) special built-in).

When a signal for which a trap has been set is received while the shell is waiting for the completion of a utility executing a foreground command, the trap associated with that signal shall not be executed until after the foreground command has completed. When the shell is waiting, by means of the *wait* utility, for asynchronous commands to complete, the reception of a signal for which a trap has been set shall cause the *wait* utility to return immediately with an exit status >128, immediately after which the trap associated with that signal shall be taken.

If multiple signals are pending for the shell for which there are associated trap actions, the order of execution of trap actions is unspecified.

2.13 Shell Execution Environment

A shell execution environment consists of the following:

- Open files inherited upon invocation of the shell, plus open files controlled by *exec*
- Working directory as set by *cd*
- File creation mask set by *umask*
- Current traps set by *trap*
- Shell parameters that are set by variable assignment (see the *set* (on page 2297) special built-in) or from the System Interfaces volume of IEEE Std. 1003.1-200x environment inherited by the shell when it begins (see the *export* (on page 2291) special built-in)
- Shell functions; see Section 2.9.5 (on page 2263)
- Options turned on at invocation or by *set*
- Process IDs of the last commands in asynchronous lists known to this shell environment; see Section 2.9.3.1 (on page 2259)
- Shell aliases; see Section 2.3.1 (on page 2239)

Utilities other than the special built-ins (see Section 2.15 (on page 2276)) shall be invoked in a separate environment that consists of the following. The initial value of these objects shall be the same as that for the parent shell, except as noted below.

- Open files inherited on invocation of the shell, open files controlled by the *exec* special built-in plus any modifications, and additions specified by any redirections to the utility
- Current working directory
- File creation mask
- If the utility is a shell script, traps caught by the shell shall be set to the default values and traps ignored by the shell shall be set to be ignored by the utility; if the utility is not a shell script, the trap actions (default or ignore) shall be mapped into the appropriate signal handling actions for the utility
- Variables with the *export* attribute, along with those explicitly exported for the duration of the command, shall be passed to the utility as System Interfaces volume of IEEE Std. 1003.1-200x environment variables

The environment of the shell process shall not be changed by the utility unless explicitly specified by the utility description (for example, *cd* and *umask*).

A subshell environment shall be created as a duplicate of the shell environment, except that signal traps set by that shell environment shall be set to the default values. Changes made to the subshell environment shall not affect the shell environment. Command substitution, commands that are grouped with parentheses, and asynchronous lists shall be executed in a subshell environment. Additionally, each command of a multi-command pipeline is in a subshell environment; as an extension, however, any or all commands in a pipeline may be executed in the current environment. All other commands shall be executed in the current shell environment.

2.14 Pattern Matching Notation

The pattern matching notation described in this section is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation described in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 9, Regular Expressions. For this reason, the description of the rules for this pattern matching notation are based on the description of regular expression notation, modified to include backslash escape processing.

2.14.1 Patterns Matching a Single Character

The following *patterns matching a single character* match a single character: *ordinary characters*, *special pattern characters*, and *pattern bracket expressions*. The pattern bracket expression also shall match a single collating element. A backslash character shall escape the following character. The escaping backslash shall be discarded.

An ordinary character is a pattern that shall match itself. It can be any character in the supported character set except for NUL, those special shell characters in Section 2.2 (on page 2236) that require quoting, and the following three special pattern characters. Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern shall match the character itself. The shell special characters always require quoting.

When unquoted and outside a bracket expression, the following three characters shall have special meaning in the specification of patterns:

? A question-mark is a pattern that shall match any character.

* An asterisk is a pattern that shall match multiple characters, as described in Section 2.14.2.

[The open bracket shall introduce a pattern bracket expression.

The description of basic regular expression bracket expressions in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3.5, RE Bracket Expression shall also apply to the pattern bracket expression, except that the exclamation mark character (’!’) shall replace the circumflex character (’^’) in its role in a *non-matching list* in the regular expression notation. A bracket expression starting with an unquoted circumflex character produces unspecified results.

When pattern matching is used where shell quote removal is not performed (such as in the argument to the *find name* primary when *find* is being called using one of the *exec* functions as defined in the System Interfaces volume of IEEE Std. 1003.1-200x, or in the *pattern* argument to the *fnmatch*( ) function), special characters can be escaped to remove their special meaning by preceding them with a backslash character. This escaping backslash is discarded. The sequence "\\" represents one literal backslash. All of the requirements and effects of quoting on ordinary, shell special, and special pattern characters shall apply to escaping in this context.

2.14.2 Patterns Matching Multiple Characters

The following rules are used to construct *patterns matching multiple characters* from *patterns matching a single character*:

1. The asterisk (’*’) is a pattern that shall match any string, including the null string.
2. The concatenation of *patterns matching a single character* is a valid pattern that shall match the concatenation of the single characters or collating elements matched by each of the concatenated patterns.

3. The concatenation of one or more *patterns matching a single character* with one or more asterisks is a valid pattern. In such patterns, each asterisk shall match a string of zero or more characters, matching the greatest possible number of characters that still allows the remainder of the pattern to match the string.

2.14.3 Patterns Used for File Name Expansion

The rules described so far in Section 2.14.1 (on page 2274) and Section 2.14.2 (on page 2274) are qualified by the following rules that apply when pattern matching notation is used for file name expansion:

1. The application shall ensure that the slash character in a path name is explicitly matched by using one or more slashes in the pattern; it cannot be matched by the asterisk or question-mark special characters or by a bracket expression. Slashes in the pattern are identified before bracket expressions; thus, a slash cannot be included in a pattern bracket expression used for file name expansion. If a slash character is found following an unescaped open square bracket character before a corresponding closing square bracket is found, the open bracket is treated as an ordinary character. For example, the pattern `"a[b/c]d"` does not match such path names as **abd** or **a/d**. It only matches a path name of literally **a[b/c]d**.

2. If a file name begins with a period (`'.'`), the application shall ensure that the period is explicitly matched by using a period as the first character of the pattern or immediately following a slash character. The leading period shall not be matched by:

   - The asterisk or question-mark special characters
   - A bracket expression containing a non-matching list, such as `"[!a]"`, a range expression, such as `"[%–0]"`, or a character class expression, such as `"[[:punct:]]"`

   It is unspecified whether an explicit period in a bracket expression matching list, such as `"[.abc]"`, can match a leading period in a file name.

3. Specified patterns are matched against existing file names and path names, as appropriate. Each component that contains a pattern character requires read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character requires search permission. For example, given the pattern:

   ```
   /foo/bar/x*/bam
   ```

   search permission is needed for directories **/** and **foo**, search and read permissions are needed for directory **bar**, and search permission is needed for each **x*** directory. If the pattern matches any existing file names or path names, the pattern shall be replaced with those file names and path names, sorted according to the collating sequence in effect in the current locale. If the pattern contains an invalid bracket expression or does not match any existing file names or path names, the pattern string shall be left unchanged.

2.15 Special Built-In Utilities

The following *special built-in* utilities shall be supported in the shell command language. The output of each command, if any, shall be written to standard output, subject to the normal redirection and piping possible with all commands.

The term *built-in* implies that the shell can execute the utility directly and does not need to search for it. An implementation can choose to make any utility a built-in; however, the special built-in utilities described here differ from regular built-in utilities in two respects:

1. A syntax error in a special built-in utility may cause a shell executing that utility to abort, while a syntax error in a regular built-in utility shall not cause a shell executing that utility to abort. (See Section 2.8.1 (on page 2255) for the consequences of errors on interactive and non-interactive shells.) If a special built-in utility encountering a syntax error does not abort the shell, its exit value shall be non-zero.
2. Variable assignments specified with special built-in utilities remain in effect after the built-in completes; this shall not be the case with a regular built-in or other utility.

The special built-in utilities in this section need not be provided in a manner accessible via the *exec* family of functions defined in the System Interfaces volume of IEEE Std. 1003.1-200x.

Some of the special built-ins are described as conforming to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines. For those that are not, the requirement in Section 1.11 (on page 2224) that "––" be recognized as a first argument to be discarded does not apply and a portable application shall not use that argument.

NAME

break — exit from for, while, or until loop

SYNOPSIS

```
break [n]
```

DESCRIPTION

The *break* utility shall exit from the smallest enclosing **for**, **while**, or **until** loop, if any; or from the *n*th enclosing loop if *n* is specified. The value of *n* is an unsigned decimal integer greater than or equal to 1. The default shall be equivalent to *n*=1. If *n* is greater than the number of enclosing loops, the last enclosing loop shall be exited from. Execution shall continue with the command immediately following the loop.

EXIT STATUS

0 Successful completion.

>0 The *n* value was not an unsigned decimal integer greater than or equal to 1.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

```
for i in * do
    if test –d "$i" then break fi done
```

RATIONALE

In early proposals, consideration was given to expanding the syntax of *break* and *continue* to refer to a label associated with the appropriate loop as a preferable alternative to the *n* method. However, this volume of IEEE Std. 1003.1-200x does reserve the namespace of command names ending with a colon. It is anticipated that a future implementation could take advantage of this and provide something like:

```
outofloop: for i in a b c d e
do
    for j in 0 1 2 3 4 5 6 7 8 9
    do
        if test –r "${i}${j}"
        then break outofloop
        fi
    done
done
```

and that this might be standardized after implementation experience is achieved.

2658 **NAME**

2659 colon — null utility

2660 **SYNOPSIS**

2661 `: [`*`argument ...`*`]`

2662 **DESCRIPTION**

2663 This utility shall only expand command *argument*s. It is used when a command is needed, as in
2664 the *then* condition of an **if** command, but nothing is to be done by the command.

2665 **OPTIONS**

2666 None.

2679 **STDERR**

2680 None.

2681 **OUTPUT FILES**

2682 None.

2683 **EXTENDED DESCRIPTION**

2684 None.

2685 **EXIT STATUS**

2686 Zero.

2687 **CONSEQUENCES OF ERRORS**

2688 None.

2689 **APPLICATION USAGE**

2690 None.

2691 **EXAMPLES**

2692
```
: ${X=abc}
if     false
then   :
else   echo $X
fi
```
2697 **abc**

2698 As with any of the special built-ins, the null utility can also have variable assignments and
2699 redirections associated with it, such as:

```
x=y : > z
```

which sets variable *x* to the value *y* (so that it persists after the null utility completes) and creates or truncates file **z**.

NAME

continue — continue for, while, or until loop

SYNOPSIS

```
continue [n]
```

DESCRIPTION

The *continue* utility shall return to the top of the smallest enclosing **for**, **while**, or **until** loop, or to the top of the *n*th enclosing loop, if *n* is specified. This involves repeating the condition list of a **while** or **until** loop or performing the next assignment of a **for** loop, and reexecuting the loop if appropriate.

The value of *n* is a decimal integer greater than or equal to 1. The default is equivalent to *n*=1. If *n* is greater than the number of enclosing loops, the last enclosing loop shall be used.

NAME

dot — execute commands in current environment

SYNOPSIS

```
. file
```

DESCRIPTION

The shell shall execute commands from the *file* in the current environment.

If *file* does not contain a slash, the shell shall use the search path specified by *PATH* to find the directory containing *file*. Unlike normal command search, however, the file searched for by the *dot* utility need not be executable. If no readable file is found, a non-interactive shell shall abort; an interactive shell shall write a diagnostic message to standard error, but this condition shall not be considered a syntax error.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

EXIT STATUS

Returns the value of the last command executed, or a zero exit status if no command is executed.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

```
cat foobar
foo=hello bar=world
. foobar
echo $foo $bar
hello world
```

2808 **RATIONALE**

2809 Some older implementations searched the current directory for the *file*, even if the value of *PATH*
2810 disallowed it. This behavior was omitted from this volume of IEEE Std. 1003.1-200x due to
2811 concerns about introducing the susceptibility to trojan horses that the user might be trying to
2812 avoid by leaving *dot* out of *PATH*.

2813 The KornShell version of *dot* takes optional arguments that are set to the positional parameters.
2814 This is a valid extension that allows a *dot* script to behave identically to a function.

2819 **CHANGE HISTORY**

2820 None.

NAME

eval — construct command by concatenating arguments

SYNOPSIS

```
eval [argument ...]
```

DESCRIPTION

The *eval* utility shall construct a command by concatenating *argument*s together, separating each with a <space> character. The constructed command shall be read and executed by the shell.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

2870 **CHANGE HISTORY**

2871 None.

NAME

exec — execute commands and open, close, or copy file descriptors

SYNOPSIS

```
exec [command [argument ...]]
```

DESCRIPTION

The *exec* utility shall open, close, and/or copy file descriptors as specified by any redirections as part of the command.

If *exec* is specified without *command* or *argument*s, and any file descriptors with numbers greater than 2 are opened with associated redirection statements, it is unspecified whether those file descriptors remain open when the shell invokes another utility. Scripts concerned that child shells could misuse open file descriptors can always close them explicitly, as shown in one of the following examples.

If *exec* is specified with *command*, it shall replace the shell with *command* without creating a new process. If *argument*s are specified, they shall be arguments to *command*. Redirection affects the current shell execution environment.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *command* is specified, *exec* shall not return to the shell; rather, the exit status of the process shall be the exit status of the program implementing *command*, which overlaid the shell. If *command* is not found, the exit status shall be 127. If *command* is found, but it is not an executable utility, the exit status shall be 126. If a redirection error occurs (see Section 2.8.1 (on page 2255)), the shell shall exit with a value in the range 1–125. Otherwise, *exec* shall return a zero exit status.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Open *readfile* as file descriptor 3 for reading:

```
exec 3< readfile
```

Open *writefile* as file descriptor 4 for writing:

```
exec 4> writefile
```

Make file descriptor 5 a copy of file descriptor 0:

```
exec 5<&0
```

Close file descriptor 3:

```
exec 3<&–
```

Cat the file **maggie** by replacing the current shell with the *cat* utility:

```
exec cat maggie
```

RATIONALE

Most historical implementations were not conformant in that:

```
foo=bar exec cmd
```

did not pass **foo** to **cmd**.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.15 (on page 2276)

CHANGE HISTORY

None.

NAME

exit — cause the shell to exit

SYNOPSIS

```
exit [n]
```

DESCRIPTION

The *exit* utility shall cause the shell to exit with the exit status specified by the unsigned decimal integer *n*. If *n* is specified, but its value is not between 0 and 255 inclusively, the exit status is undefined.

A *trap* on **EXIT** shall be executed before the shell terminates, except when the *exit* utility is invoked in that *trap* itself, in which case the shell shall exit immediately.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The exit status shall be *n*, if specified. Otherwise, the value shall be the exit value of the last command executed, or zero if no command was executed. When *exit* is executed in a *trap* action, the last command is considered to be the command that executed immediately preceding the *trap* action.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Exit with a *true* value:

```
exit 0
```

Exit with a *false* value:

```
exit 1
```

RATIONALE

As explained in other sections, certain exit status values have been reserved for special uses and should be used by applications only for those purposes:

126 A file to be executed was found, but it was not an executable utility.

127 A utility to be executed was not found.

>128 A command was interrupted by a signal.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.15 (on page 2276)

CHANGE HISTORY

NAME

export — set export attribute for variables

SYNOPSIS

```
export name[=word]...
export –p
```

DESCRIPTION

The shell shall give the export attribute to the variables corresponding to the specified *name*s, which shall cause them to be in the environment of subsequently executed commands.

The *export* special built-in shall support the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

When –**p** is specified, *export* shall write to the standard output the names and values of all exported variables, in the following format:

```
"export %s=%s\n", <name>, <value>
```

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results.

When no arguments are given, the results are unspecified.

EXIT STATUS

Zero.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Export *PWD* and *HOME* variables:

```
export PWD HOME
```

Set and export the *PATH* variable:

```
export PATH=/local/bin:$PATH
```

Save and restore all exported variables:

```
export –p > temp-file
unset a lot of variables
... processing
. temp-file
```

RATIONALE

Some historical shells use the no-argument case as the functional equivalent of what is required here with **–p**. This feature was left unspecified because it is not historical practice in all shells, and some scripts may rely on the now-unspecified results on their implementations. Attempts to specify the **–p** output as the default case were unsuccessful in achieving consensus. The **–p** option was added to allow portable access to the values that can be saved and then later restored using; for example, a *dot* script.

FUTURE DIRECTIONS

None.

NAME

readonly — set read-only attribute for variables

SYNOPSIS

```
readonly name[=word]...
readonly -p
```

DESCRIPTION

The variables whose *name*s are specified shall be given the *readonly* attribute. The values of variables with the *readonly* attribute cannot be changed by subsequent assignment, nor can those variables be unset by the *unset* utility.

The *readonly* special built-in shall support the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

When **−p** is specified, *readonly* writes to the standard output the names and values of all read-only variables, in the following format:

```
"readonly %s=%s\n", <name>, <value>
```

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same attribute-setting results.

When no arguments are given, the results are unspecified.

3101 None.

3102 **EXAMPLES**

3103
```
readonly HOME PWD
```

3104 **RATIONALE**

3105 Some historical shells preserve the read-only attribute across separate invocations. This volume
3106 of IEEE Std. 1003.1-200x allows this behavior, but does not require it.

3107 The **−p** option allows portable access to the values that can be saved and then later restored
3108 using; for example, a *dot* script. Also see the RATIONALE for *export* (on page 2291) for a
3109 description of the no-argument and **−p** output cases and a related example.

3110 Read-only functions were considered, but they were omitted as not being historical practice or
3111 particularly useful. Furthermore, functions must not be *readonly* across invocations to preclude
3112 *spoofing* (spoofing is the term for the practice of creating a program that acts like a well-known
3113 utility with the intent of subverting the real intent of the user) of administrative or security-
3114 relevant (or security-conscious) shell scripts.

3115 **FUTURE DIRECTIONS**

3116 None.

3117 **SEE ALSO**

3118 Section 2.15 (on page 2276)

3119 **CHANGE HISTORY**

NAME

return — return from a function

SYNOPSIS

```
return [n]
```

DESCRIPTION

The *return* utility shall cause the shell to stop executing the current function or *dot* script. If the shell is not currently executing a function or *dot* script, the results are unspecified.

OPTIONS

None.

OPERANDS

None.

STDIN

None.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

None.

STDOUT

None.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The value of the special parameter `'?'` shall be set to *n*, an unsigned decimal integer, or to the exit status of the last command executed if *n* is not specified. If the value of *n* is greater than 255, the results are undefined. When *return* is executed in a *trap* action, the last command is considered to be the command that executed immediately preceding the *trap* action.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The behavior of *return* when not in a function or *dot* script differs between the System V shell and the KornShell. In the System V shell this is an error, whereas in the KornShell, the effect is the same as *exit*.

The results of returning a number greater than 255 are undefined because of differing practices in the various historical implementations. Some shells AND out all but the low-order 8 bits; others allow larger values, but not of unlimited size.

See the discussion of appropriate exit status values under *exit* (on page 2289).

FUTURE DIRECTIONS

None.

NAME

set — set or unset options and positional parameters

SYNOPSIS

XSI `set [–abCefmnuvx][–h][–o option][argument...]`

XSI `set [+abCefmnuvx][+h][+o option][argument...]`

`set ––[argument...]`

`set –o`

`set +o`

DESCRIPTION

If no options or *argument*s are specified, *set* shall write the names and values of all shell variables in the collation sequence of the current locale. Each *name* shall start on a separate line, using the format:

`"%s=%s\n", <name>, <value>`

The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the shell, setting or resetting, as far as possible, the variables that are currently set. Read-only variables cannot be reset; see the description of shell quoting in Section 2.2 (on page 2236).

When options are specified, they shall set or unset attributes of the shell, as described below. When *argument*s are specified, they cause positional parameters to be set or unset, as described below. Setting or unsetting attributes and positional parameters are not necessarily related actions, but they can be combined in a single invocation of *set*.

The *set* special built-in shall support the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines except that options can be specified with either a leading hyphen (meaning enable the option) or plus sign (meaning disable it).

Implementations shall support the options in the following list in both their hyphen and plus-sign forms. These options can also be specified as options to *sh*.

–a When this option is on, the export attribute shall be set for each variable to which an assignment is performed; see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 4.16, Variable Assignment. If the assignment precedes a utility name in a command, the export attribute shall not persist in the current execution environment after the utility completes, with the exception that preceding one of the special built-in utilities causes the export attribute to persist after the built-in has completed. If the assignment does not precede a utility name in the command, or if the assignment is a result of the operation of the *getopts* or *read* utilities, the export attribute shall persist until the variable is unset.

–b This option is supported if the system supports the User Portability Utilities option. It shall cause the shell to notify the user asynchronously of background job completions. The following message is written to standard error:

`"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name>`

where the fields shall be as follows:

<*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* `"%+"` or `"%%"`. The character `'–'` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* `"%–"`. For other jobs, this field is a <space> character. At most one job can be identified with `'+'` and at most one job can be identified

3217 with '−'. If there is any suspended job, then the current job shall be a
3218 suspended job. If there are at least two suspended jobs, then the previous
3219 job also shall be a suspended job.

3220 <*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*,
3221 and *kill* utilities. Using these utilities, the job can be identified by
3222 prefixing the job number with '%'.

3223 <*status*> Unspecified.

3224 <*job-name*> Unspecified.

3225 When the shell notifies the user a job has been completed, it may remove the job's process
3226 ID from the list of those known in the current shell execution environment; see Section
3227 2.9.3.1 (on page 2259). Asynchronous notification shall not be enabled by default.

3228 **−C** (Uppercase C.) Prevent existing files from being overwritten by the shell's '>' redirection
3229 operator (see Section 2.7.2 (on page 2252)); the ">|" redirection operator shall override this
3230 *noclobber* option for an individual file.

3231 **−e** When this option is on, if a simple command fails for any of the reasons listed in Section
3232 2.8.1 (on page 2255) or returns an exit status value >0, and is not part of the compound list
3233 following a **while**, **until**, or **if** keyword, and is not a part of an AND or OR list, and is not a
3234 pipeline preceded by the **!** reserved word, then the shell shall immediately exit.

3235 **−f** The shell shall disable path name expansion.

3236 XSI **−h** Locate and remember utilities invoked by functions as those functions are defined (the
3237 utilities are normally located when the function is executed).

3238 **−m** This option is supported if the system supports the User Portability Utilities option. All jobs
3239 shall be run in their own process groups. Immediately before the shell issues a prompt after
3240 completion of the background job, a message reporting the exit status of the background job
3241 shall be written to standard error. If a foreground job stops, the shell shall write a message
3242 to standard error to that effect, formatted as described by the *jobs* utility. In addition, if a job
3243 changes status other than exiting (for example, if it stops for input or output or is stopped
3244 by a SIGSTOP signal), the shell shall write a similar message immediately prior to writing
3245 the next prompt. This option is enabled by default for interactive shells.

3246 **−n** The shell shall read commands but does not execute them; this can be used to check for
3247 shell script syntax errors. An interactive shell may ignore this option.

3248 **−o** Write the current settings of the options to standard output in an unspecified format.

3249 **+o** Write the current option settings to standard output in a format that is suitable for reinput
3250 to the shell as commands that achieve the same options settings.

3251 **−o** *option*
3252 This option is supported if the system supports the User Portability Utilities option. It shall
3253 set various options, many of which shall be equivalent to the single option letters. The
3254 following values of *option* shall be supported:

3255 *allexport* Equivalent to **−a**.

3256 *errexit* Equivalent to **−e**.

3257 *ignoreeof* Prevent an interactive shell from exiting on end-of-file. This setting prevents |
3258 accidental logouts when <control>-D is entered. A user shall explicitly *exit* to |
3259 leave the interactive shell.

monitor Equivalent to **–m**. This option is supported if the system supports the User Portability Utilities option.

noclobber Equivalent to **–C** (uppercase C).

noglob Equivalent to **–f**.

noexec Equivalent to **–n**.

nolog Prevent the entry of function definitions into the command history; see **Command History List** (on page 3064).

notify Equivalent to **–b**.

nounset Equivalent to **–u**.

verbose Equivalent to **–v**.

vi Allow shell command line editing using the built-in *vi* editor. Enabling *vi* mode shall disable any other command line editing mode provided as an implementation extension.

It need not be possible to set *vi* mode on for certain block-mode terminals.

xtrace Equivalent to **–x**.

–u The shell writes a message to standard error when it tries to expand a variable that is not set and immediately exit. An interactive shell shall not exit.

–v The shell writes its input to standard error as it is read.

–x The shell writes to standard error a trace for each command after it expands the command and before it executes it. It is unspecified whether the command that turns tracing off is traced.

The default for all these options is off (unset) unless the shell was invoked with them on; see *sh*.

The remaining arguments shall be assigned in order to the positional parameters. The special parameter '#' shall be set to reflect the number of positional parameters. All positional parameters shall be unset before any new values are assigned.

The special argument "—-" immediately following the *set* command name can be used to delimit the arguments if the first argument begins with '+' or '–', or to prevent inadvertent listing of all shell variables when there are no arguments. The command *set*–– without *argument* shall unset all positional parameters and set the special parameter '#' to zero.

EXAMPLES

Write out all variables and their values:

```
set
```

Set $1, $2, and $3 and set "$#" to 3:

```
set c a b
```

Turn on the **–x** and **–v** options:

```
set –xv
```

Unset all positional parameters:

```
set ––
```

Set $1 to the value of **–x**, even if **x** begins with '–' or '+':

```
set –– "$x"
```

Set the positional parameters to the expansion of **x**, even if **x** expands with a leading '–' or '+':

```
set –– $x
```

RATIONALE

The *set* –– form is listed specifically in the SYNOPSIS even though this usage is implied by the Utility Syntax Guidelines. The explanation of this feature removes any ambiguity about whether the *set* –– form might be misinterpreted as being equivalent to *set* without any options or arguments. The functionality of this form has been adopted from the KornShell. In System V, *set* –– only unsets parameters if there is at least one argument; the only way to unset all parameters is to use *shift*. Using the KornShell version should not affect System V scripts because there should be no reason to issue it without arguments deliberately; if it were issued as, for example:

```
set –– "$@"
```

and there were in fact no arguments resulting from "$@", unsetting the parameters would have no result.

The *set* + form in early proposals was omitted as being an unnecessary duplication of *set* alone and not widespread historical practice.

The *noclobber* option was changed to allow *set* −**C** as well as the *set* −**o** *noclobber* option. The single-letter version was added so that the historical "$−" paradigm would not be broken; see Section 2.5.2 (on page 2241).

The −**h** flag is related to command name hashing and is only required on XSI-conformant systems.

The following *set* flags were omitted intentionally with the following rationale:

−**k** The −**k** flag was originally added by the author of the Bourne shell to make it easier for users of pre-release versions of the shell. In early versions of the Bourne shell the construct *set name=value*, had to be used to assign values to shell variables. The problem with −**k** is that the behavior affects parsing, virtually precluding writing any compilers. To explain the behavior of −**k**, it is necessary to describe the parsing algorithm, which is implementation-defined. For example:

```
set −k; echo name=value
```

and:

```
set x−−k
echo name=value
```

behave differently. The interaction with functions is even more complex. What is more, the −**k** flag is never needed, since the command line could have been reordered.

−**t** The −**t** flag is hard to specify and almost never used. The only known use could be done with here-documents. Moreover, the behavior with *ksh* and *sh* differs. The reference page says that it exits after reading and executing one command. What is one command? If the input is *date*;*date*, *sh* executes both *date* commands while *ksh* does only the first.

Consideration was given to rewriting *set* to simplify its confusing syntax. A specific suggestion was that the *unset* utility should be used to unset options instead of using the non-*getopt*( )-able +*option* syntax. However, the conclusion was reached that the historical practice of using +*option* was satisfactory and that there was no compelling reason to modify such widespread historical practice.

The −**o** option was adopted from the KornShell to address user needs. In addition to its generally friendly interface, −**o** is needed to provide the *vi* command line editing mode, for which historical practice yields no single-letter option name. (Although it might have been possible to invent such a letter, it was recognized that other editing modes would be developed and −**o** provides ample name space for describing such extensions.)

Historical implementations are inconsistent in the format used for −**o** option status reporting. The **+o** format without an option-argument was added to allow portable access to the options that can be saved and then later restored using, for instance, a dot script.

Historically, *sh* did trace the command *set* **+x**, but *ksh* did not.

The *ignoreeof* setting prevents accidental logouts when the end-of-file character (typically <control>-D) is entered. A user shall explicitly *exit* to leave the interactive shell.

The *set* −**m** option was added to apply only to the UPE because it applies primarily to interactive use, not shell script applications.

The ability to do asynchronous notification became available in the 1988 version of the KornShell. To have it occur, the user had to issue the command:

```
trap "jobs –n" CLD
```

The C shell provides two different levels of an asynchronous notification capability. The environment variable *notify* is analogous to what is done in *set* –**b** or *set* –**o** *notify*. When set, it notifies the user immediately of background job completions. When unset, this capability is turned off.

The other notification ability comes through the built-in utility *notify*. The syntax is:

```
notify [%job ... ]
```

By issuing *notify* with no operands, it causes the C shell to notify the user asynchronously when the state of the current job changes. If given operands, *notify* asynchronously informs the user of changes in the states of the specified jobs.

To add asynchronous notification to the POSIX shell, neither the KornShell extensions to *trap*, nor the C shell *notify* environment variable seemed appropriate (*notify* is not a proper POSIX environment variable name).

The *set* –**b** option was selected as a compromise.

The *notify* built-in was considered to have more functionality than was required for simple asynchronous notification.

FUTURE DIRECTIONS

None.

Section 2.15 (on page 2276)

CHANGE HISTORY

Issue 6

The obsolescent *set* command name followed by '–' has been removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *nolog* option is added to *set* –**o**.

NAME

shift — shift positional parameters

SYNOPSIS

```
shift [n]
```

DESCRIPTION

The positional parameters shall be shifted. Positional parameter 1 shall be assigned the value of parameter (1+*n*), parameter 2 shall be assigned the value of parameter (2+*n*), and so on. The parameters represented by the numbers `"$#"` down to `"$#–n+1"` shall be unset, and the parameter `'#'` is updated to reflect the new number of positional parameters.

The value *n* shall be an unsigned decimal integer less than or equal to the value of the special parameter `'#'`. If *n* is not given, it shall be assumed to be 1. If *n* is 0, the positional and special parameters are not changed.

NAME

times — write process times

SYNOPSIS

```
times
```

DESCRIPTION

Write the accumulated user and system times for the shell and for all of its child processes, in the following POSIX locale format:

```
"%dm%fs %dm%fs\n%dm%fs %dm%fs\n", <shell user minutes>,
    <shell user seconds>, <shell system minutes>,
    <shell system seconds>, <children user minutes>,
    <children user seconds>, <children system minutes>,
    <children system seconds>
```

The four pairs of times correspond to the members of the **<sys/times.h> tms** structure (defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 13, Headers) as returned by *times*( ): *tms_utime*, *tms_stime*, *tms_cutime*, and *tms_cstime*, respectively.

NAME

trap — trap signals

SYNOPSIS

```
trap [action condition ...]
```

DESCRIPTION

If *action* is `'-'`, the shell shall reset each *condition* to the default value. If *action* is null (`""`), the shell shall ignore each specified *condition* if it arises. Otherwise, the argument *action* shall be read and executed by the shell when one of the corresponding conditions arises. The action of *trap* shall override a previous action (either default action or one explicitly set). The value of `"$?"` after the *trap* action completes shall be the value it had before *trap* was invoked.

The condition can be EXIT, 0 (equivalent to EXIT), or a signal specified using a symbolic name, without the SIG prefix, as listed in the tables of signal names in the **<signal.h>** header defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 13, Headers; for example, HUP, INT, QUIT, TERM. Implementations may permit lowercase signal names or names with the SIG prefix as an extension. Setting a trap for SIGKILL or SIGSTOP produces undefined results.

The environment in which the shell executes a *trap* on EXIT shall be identical to the environment immediately after the last command executed before the *trap* on EXIT was taken.

Each time *trap* is invoked, the *action* argument shall be processed in a manner equivalent to:

```
eval "$action"
```

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps shall remain in place for a given shell until explicitly changed with another *trap* command.

When a subshell is entered, traps that are not being ignored are set to the default actions. This does not imply that the *trap* command cannot be used within the subshell to set new traps.

The *trap* command with no arguments shall write to standard output a list of commands associated with each condition. The format shall be:

```
"trap -- %s %s ...\n", <action>, <condition> ...
```

The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
...
eval "$save_traps"
```

XSI XSI-conformant systems also allow numeric signal numbers for the conditions corresponding to the following signal names:

Signal Number	Signal Name
1	SIGHUP
2	SIGINT
3	SIGQUIT
6	SIGABRT
9	SIGKILL
14	SIGALRM
15	SIGTERM

The *trap* special built-in shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

OPTIONS

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the trap name or number is invalid, a non-zero exit status shall be returned; otherwise, zero shall be returned. For both interactive and non-interactive shells, invalid signal names or numbers shall not be considered a syntax error and do not cause the shell to abort.

CONSEQUENCES OF ERRORS

None.

APPLICATION USAGE

None.

EXAMPLES

Write out a list of all traps and actions:

```
trap
```

Set a trap so the *logout* utility in the directory referred to by the *HOME* environment variable executes when the shell terminates:

```
trap '$HOME/logout' EXIT
```

or:

```
trap '$HOME/logout' 0
```

Unset traps on INT, QUIT, TERM, and EXIT:

```
trap - INT QUIT TERM EXIT
```

RATIONALE

Implementations may permit lowercase signal names as an extension. Implementations may also accept the names with the SIG prefix; no known historical shell does so. The *trap* and *kill* utilities in this volume of IEEE Std. 1003.1-200x are now consistent in their omission of the SIG prefix for signal names. Some *kill* implementations do not allow the prefix, and *kill* **–l** lists the signals without prefixes.

Trapping SIGKILL or SIGSTOP is syntactically accepted by some historical implementations, but it has no effect. Portable POSIX applications cannot attempt to trap these signals.

The output format is not historical practice. Since the output of historical *trap* commands is not portable (because numeric signal values are not portable) and had to change to become so, an opportunity was taken to format the output in a way that a shell script could use to save and then later reuse a trap if it wanted.

The KornShell uses an **ERR** trap that is triggered whenever *set* **–e** would cause an exit. This is allowable as an extension, but was not mandated, as other shells have not used it.

The text about the environment for the EXIT trap invalidates the behavior of some historical versions of interactive shells which, for example, close the standard input before executing a trap on 0. For example, in some historical interactive shell sessions the following trap on 0 would always print "––":

```
trap 'read foo; echo "-$foo-"' 0
```

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.15 (on page 2276)

CHANGE HISTORY

Issue 6

XSI-conforming implementations provide the mapping of signal names to numbers given above (previously this had been marked obsolescent). Other implementations need not provide this optional mapping.

3626 **NAME**

3627 unset — unset values and attributes of variables and functions

3628 **SYNOPSIS**

3629 `unset [–fv] name ...`

3630 **DESCRIPTION**

3631 Each variable or function specified by *name* shall be unset.

3632 If **–v** is specified, *name* refers to a variable name and the shall unset it and remove it from
3633 the environment. Read-only variables cannot be unset.

3634 If **–f** is specified, *name* refers to a function and the shell shall unset the function definition.

3635 If neither **–f** nor **–v** is specified, *name* refers to a variable; if a variable by that name does not
3636 exist, it is unspecified whether a function by that name, if any, shall be unset.

3637 Unsetting a variable or function that was not previously set shall not be considered an error and
3638 does not cause the shell to abort.

3639 The *unset* special built-in shall support the Base Definitions volume of IEEE Std. 1003.1-200x, |
3640 Section 12.2, Utility Syntax Guidelines. |

3641 Note that:

3642 `VARIABLE=`

3643 is not equivalent to an *unset* of **VARIABLE**; in the example, **VARIABLE** is set to `""`. Also, the
3644 variables that can be *unset* should not be misinterpreted to include the special parameters (see
3645 Section 2.5.2 (on page 2241)).

3646 **OPTIONS**

3647 None.

3648 **OPERANDS**

3649 None.

3650 **STDIN**

3651 None.

3652 **INPUT FILES**

3653 None.

3654 **ENVIRONMENT VARIABLES**

3655 None.

3656 **ASYNCHRONOUS EVENTS**

3657 None.

3658 **STDOUT**

3659 None.

3660 **STDERR**

3661 None.

3662 **OUTPUT FILES**

3663 None.

3664 **EXTENDED DESCRIPTION**

3665 None.

3666 **EXIT STATUS**

3667 0 All *name* operands were successfully unset.

3668 >0 At least one *name* could not be unset.

3669 **CONSEQUENCES OF ERRORS**

3670 None.

3671 **APPLICATION USAGE**

3672 None.

3673 **EXAMPLES**

3674 Unset *VISUAL* variable:

3675
```
unset –v VISUAL
```

3676 Unset the functions **foo** and **bar**:

3677
```
unset –f foo bar
```

3678 **RATIONALE**

3679 Consideration was given to omitting the **–f** option in favor of an *unfunction* utility, but the
3680 standard developers decided to retain historical practice.

3681 The **–v** option was introduced because System V historically used one name space for both
3682 variables and functions. When *unset* is used without options, System V historically unset either a
3683 function or a variable, and there was no confusion about which one was intended. A portable
3684 POSIX application can use *unset* without an option to unset a variable, but not a function; the **–f**
3685 option must be used.

3686 **FUTURE DIRECTIONS**

3687 None.

Chapter 3

Batch Environment Services

BE This chapter describes the services and utilities that shall be implemented on all systems that claim conformance to the Batch Environment option. This functionality is dependent on support of this option (and the rest of this section is not further shaded for this option).

3.1 General Concepts

3.1.1 Batch Client-Server Interaction

Batch jobs are created and managed by batch servers. A batch client interacts with a batch server to access batch services on behalf of the user. In order to use batch services, a user must have access to a batch client.

A batch server is a computational entity, such as a daemon process, that provides batch services. Batch servers route, queue, modify, and execute batch jobs on behalf of batch clients.

The batch utilities described in this volume of IEEE Std. 1003.1-200x (and listed in Table 3-1 (on page 2314)) are clients of batch services; they allow users to perform actions on the job such as creating, modifying, and deleting batch jobs from a shell command line. Although these batch utilities may be said to accomplish certain services, they actually obtain services on behalf of a user by means of requests to batch servers.

Table 3-1 Batch Utilities

qalter	*qmove*	*qrls*	*qstat*
qdel	*qmsg*	*qselect*	*qsub*
qhold	*qrerun*	*qsig*	

Client-server interaction takes place by means of the batch requests defined in this chapter. Because direct access to batch jobs and queues is limited to batch servers, clients and servers of different implementations can interoperate, since dependencies on private structures for batch jobs and queues are limited to batch servers. Also, batch servers may be clients of other batch servers.

3.1.2 Batch Queues

Two types of batch queue are described: *routing queues* and *execution queues*. When a batch job is placed in a routing queue, it is a candidate for routing. A batch job is removed from routing queues under the following conditions:

- The batch job has been routed to another queue.
- The batch job has been deleted from the batch queue.
- The batch job has been aborted.

When a batch job is placed in an execution queue, it is a candidate for execution.

A batch job is removed from an execution queue under the following conditions:

- The batch job has been executed and exited.
- The batch job has been aborted.
- The batch job has been deleted from the batch queue.
- The batch job has been moved to another queue.

Access to a batch queue is limited to the batch server that manages the batch queue. Clients never access a batch queue or a batch job directly, either to read or write information; all client access to batch queues or jobs takes place through batch servers.

3.1.3 Batch Job Creation

When a batch server creates a batch job on behalf of a client, it assigns a batch job identifier to the job. A batch job identifier consists of both a sequence number that is unique among the sequence numbers issued by that server and the name of the server. Since the batch server name is unique within a name space, the job identifier is likewise unique within the name space.

The batch server that creates a batch job returns the batch server-assigned job identifier to the client that requested the job creation. If the batch server routes or moves the job to another server, it sends the job identifier with the job. Once assigned, the job identifier of a batch job never changes.

3.1.4 Batch Job Tracking

Since a batch job may be moved after creation, the batch server name component of the job identifier does not always indicate the location of the job. An implementation may provide a batch job tracking mechanism, in which case the user generally does not need to know the location of the job. However, an implementation is not required to provide a batch job tracking mechanism, in which case the user must find routed jobs by probing the possible destinations.

3.1.5 Batch Job Routing

To route a batch job, a batch server either moves the job to some other queue that is managed by the batch server, or requests that some other batch server accept the job.

Each routing queue has one or more queues to which it can route batch jobs. The batch server administrator creates routing queues.

A batch server may route a batch job from a routing queue to another routing queue. Batch servers shall prevent or otherwise handle cases of circular routing paths. As a deferred service, a batch server routes jobs from the routing queues that it manages. The algorithm by which a batch server selects a batch queue to which to route a batch job is implementation-defined.

A batch job need not be eligible for routing to all the batch queues fed by the routing queue from which it is routed. A batch server that has been asked to accept the job may reject the request if the job requires resources that are unavailable to that batch server, or if the client is not authorized to access the batch server.

Batch servers may route high-priority jobs before low-priority jobs, but, on other than overloaded systems, the effect may be imperceptible to the user. If all the batch servers fed by a routing queue reject requests to accept the job for reasons that are permanent, the batch server that manages the job aborts the job. If all or some rejections are temporary, the batch server should try to route the job again at some later point.

The conformance document for an implementation shall list the reasons for rejecting the routing of a batch job. The conformance document shall indicate the reasons for which the routing should be retried later and the reasons for which the job should be aborted.

3.1.6 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path* attribute of the job. The script is passed to the program as its standard input. An implementation of the batch server may pass the script to the program by other means. The implementation shall document the alternate means in the conformance document. At the time a batch job begins execution, it is defined to enter the RUNNING state. The primary program that is executed by a batch job is typically, though not necessarily, a shell program.

A batch server executes eligible jobs as a deferred service—no client request is necessary once the batch job is created and eligible. However, the attributes of a batch job, such as the job hold type, may render the job ineligible. A batch server scans the execution queues that it manages for jobs that are eligible for execution. The algorithm by which the batch server selects eligible jobs for execution is implementation-defined.

As part of creating the process for the batch job, the batch server opens the standard output and standard error streams of the session.

The attributes of a batch job may indicate that the batch server that executes the job is to send mail to a list of users at the time it begins execution of the job.

3.1.7 Batch Job Exit

When the session leader of an executing job terminates, the job exits. As part of exiting a batch job, the batch server that manages the job shall remove the job from the batch queue in which it resides. The server shall transfer output files of the job to a location described by the attributes of the job.

The attributes of a batch job may indicate that the batch server that manages the job should send mail to a list of users at the time the job exits.

3.1.8 Batch Job Abort

A batch server aborts jobs for which a required deferred service cannot be performed. The attributes of a batch job may indicate that the batch server that aborts the job shall send mail to a list of users at the time it aborts the job.

3.1.9 Batch Authorization

In order to access batch services, a user must have execute access to a batch client. For example, to use the command language interface defined in this section, the user must be able to execute the programs that embody those utilities.

Clients, such as the batch environment utilities (marked BE), access batch services by means of requests to one or more batch servers. To acquire the services of any given batch server, the user identifier under which the client runs must be authorized to use that batch server.

The user with an associated user name that creates a batch job owns the job and can perform actions such as read, modify, delete, and move.

A user identifier of the same value at a different host need not be the same user. For example, user name *smith* at host **alpha** may or may not represent the same person as user name *smith* at host **beta**. Likewise, the same person may have access to different user names on different hosts.

An implementation may optionally provide an authorization mechanism that permits one user name to access jobs under another user name.

A process on a client host may be authorized to run processes under multiple user names at a batch server host. Where appropriate, the utilities defined in this volume of IEEE Std. 1003.1-200x provide a means for a user to choose from among such user names when creating or modifying a batch job.

3.1.10 Batch Administration

The processing of a batch job by a batch server is affected by the attributes of the job. The processing of a batch job may also be affected by the attributes of the batch queue in which the job resides and by the status of the batch server that manages the job.

A batch administrator is a user that is authorized to modify all the attributes of queues and jobs and to change the status of a batch server. A batch operator is a user that is authorized to modify some, but not all, of the attributes of jobs and queues, and may change the status of the batch server.

3.1.11 Batch Notification

Whereas batch servers are persistent entities, clients are often transient. For example, the *qsub* utility creates a batch job and exits. For this reason, batch servers notify users of batch job events by sending mail to the user that owns the job, or to other designated users.

3.2 Batch Services

The presence of Batch Environment option services is indicated by the configuration variable POSIX2_PBS. A conforming batch server provides services as defined in this section.

A batch server provides batch services in two ways:

1. The batch server provides a service at the request of a client.
2. The batch server provides a deferred service as a result of a change in conditions monitored by the batch server.

If a batch server cannot complete a request, it rejects the request. If a batch server cannot complete a deferred service for a batch job, the batch server aborts the batch job. Table 3-2 is a summary of environment variables that shall be supported by an implementation of the batch server and utilities.

Table 3-2 Environment Variable Summary

Variable	Description
PBS_DPREFIX	Defines the directive prefix (see *qsub*)
PBS_ENVIRONMENT	Batch Job is batch or interactive (see Section 3.2.2.1 (on page 2319))
PBS_JOBID	The *job_identifier* attribute of job (see Section 3.2.3.8 (on page 2331))
PBS_JOBNAME	The *job_name* attribute of job (see Section 3.2.3.8 (on page 2331))
PBS_O_HOME	Defines the *HOME* of the batch client (see *qsub*)
PBS_O_HOST	Defines the host name of the batch client (see *qsub*)
PBS_O_LANG	Defines the *LANG* of the batch client (see *qsub*)
PBS_O_LOGNAME	Defines the *LOGNAME* of the batch client (see *qsub*)
PBS_O_MAIL	Defines the *MAIL* of the batch client (see *qsub*)
PBS_O_PATH	Defines the *PATH* of the batch client (see *qsub*)
PBS_O_QUEUE	Defines the submit queue of the batch client (see *qsub*)
PBS_O_SHELL	Defines the *SHELL* of the batch client (see *qsub*)
PBS_O_TZ	Defines the *TZ* of the batch client (see *qsub*)
PBS_O_WORKDIR	Defines the working directory of the batch client (see *qsub*)
PBS_QUEUE	Defines the initial execution queue (see Section 3.2.2.1 (on page 2319))

3.2.1 Batch Job States

A batch job is always in one of several states: QUEUED, RUNNING, HELD, WAITING, EXITING, or TRANSITING. The state of a batch job determines the types of requests that the batch server that manages the batch job can accept for the batch job. A batch server changes the state of a batch job either in response to service requests from clients or as a result of deferred services, such as job execution or job routing.

A batch job that is in the QUEUED state resides in a queue but is still pending either execution or routing, depending on the queue type.

A batch server that queues a batch job in a routing queue shall put the batch job in the QUEUED state. A batch server that puts a batch job in an execution queue, but has not yet executed the batch job, shall put the batch job in the QUEUED state. A batch job that resides in an execution queue and is executing is defined to be in the RUNNING state. While a batch job is in the RUNNING state, a session leader is associated with the batch job.

A batch job that resides in an execution queue, but is ineligible to run because of a hold attribute, is defined to be in the HELD state.

A batch job that is not held, but must wait until a future date and time before executing, is defined to be in the WAITING state.

When the session leader associated with a running job exits, the batch job shall be placed in the EXITING state.

A batch job for which the session leader has terminated is defined to be in the EXITING state, and the batch server that manages such a batch job cannot accept job modification requests that affect the batch job. While a batch job is in the EXITING state, the batch server that manages the batch job is staging output files and notifying clients of job completion. Once a batch job has exited, it no longer exists as an object managed by a batch server.

A batch job that is being moved from a routing queue to another queue is defined to be in the TRANSITING state.

When a batch job in a routing queue has been selected to be moved to a new destination, then the batch job is in either the QUEUED state or the TRANSITING state, depending on the batch server implementation.

Batch jobs with either a *Execution_Time* attribute value set in the future or a *Hold_Types* attribute of value not equal to NO_HOLD, or both, may be routed or held in the routing queue. An implementation shall document the treatment of jobs with the *Execution_Time* or *Hold_Types* attributes in a routing queue.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has a *Hold_Types* attribute value of other than NO_HOLD, then the job should be in the HELD state.

Note: The effect of a hold upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- An *Execution_Time* attribute in the past

then the batch job shall be in the QUEUED state.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- A *Execution_Time* attribute in the future

then the batch job may be in the WAITING state.

Note: The effect of a future execution time upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

Table 3-3 describes the next state of a batch job, given the current state of the batch job and the type of request. Table 3-4 (on page 2321) describes the response of a batch server to a request, given the current state of the batch job and the type of request.

3.2.2 Deferred Batch Services

This section describes the deferred services performed by batch servers: job execution, job routing, job exit, job abort, and the rerunning of jobs after a restart.

3.2.2.1 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path_List* attribute of the batch job. The script is passed to the program as its standard input. An implementation of the batch server may pass the script to the program by other means. The implementation shall document the alternate means in the conformance document. At the time a batch job begins execution, it is defined to enter the RUNNING state.

Table 3-3 Next State Table

Request Type	Current State

e Error

A batch server that has an execution queue containing jobs is said to own the queue and manage the batch jobs in that queue. A batch server that has been started shall execute the batch jobs in the execution queues owned by the batch server. The batch server shall schedule for execution those jobs in the execution queues that are in the QUEUED state. The algorithm for scheduling jobs is implementation-defined.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_ENVIRONMENT*, the value of which is the string PBS_BATCH encoded in the portable character set.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_QUEUE*, the value of which is the name of the execution queue of the batch job encoded in the portable character set.

To rerun a batch job is to requeue a batch job that is currently executing and then kill the session leader of the executing job by sending a SIGKILL prior to completion; see Section 3.2.3.11 (on page 2333). A batch server that reruns a batch job shall append the standard output and standard error files of the batch job to the corresponding files of the previous execution, if they exist, with appropriate annotation. If either file does not exist, that file shall be created as in normal execution.

Table 3-4 Results / Output Table

Request Type	Current State

Legend

O OK

e Error message

The execution of a batch job by a batch server is controlled by job, queue, and server attributes, as defined in this section.

Account_Name Attribute

Batch accounting is an optional feature of batch servers. If a batch server implements accounting, the statements in this section apply and the configuration variable POSIX2_PBS_ACCOUNTING shall be set to 1.

A batch server that executes a batch job shall charge the account named in the *Account_Name* attribute of the batch job for resources consumed by the batch job.

If the *Account_Name* attribute of the batch job is absent from the batch job attribute list or is altered while the batch job is in execution, the batch server action is implementation-defined.

Checkpoint Attribute

Batch checkpointing is an optional feature of batch servers. If a batch server implements checkpointing, the statements in this section apply and the configuration variable POSIX2_PBS_CHECKPOINT shall be set to 1.

There are two attributes associated with the checkpointing feature: *Checkpoint* and *Minimum_Cpu_Interval*. *Checkpoint* is a batch job attribute, while *Minimum_Cpu_Interval* is a queue attribute. An implementation that does not support checkpointing shall support the *Checkpoint* job attribute to the extent that the batch server shall maintain and pass this attribute to other servers.

The behavior of a batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_UNSPECIFIED is implementation-defined. The implementation shall document the behavior of the batch server. A batch server that executes a batch job for which the

value of the *Checkpoint* attribute is NO_CHECKPOINT shall not checkpoint the batch job.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_SHUTDOWN shall checkpoint the batch job only when the batch server accepts a request to shut down during the time when the batch job is in the RUNNING state.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_MIN_CPU_INTERVAL shall checkpoint the batch job at the interval specified by the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected. The *Minimum_Cpu_Interval* attribute shall be specified in units of CPU minutes.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is an unsigned integer shall checkpoint the batch job at an interval that is the value of either the *Checkpoint* attribute, or the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected, whichever is greater. Both intervals shall be in units of CPU minutes. When the *Minimum_Cpu_Interval* attribute is greater than the *Checkpoint* attribute, the batch job shall write a warning message to the standard error stream of the batch job.

Error_Path Attribute

The *Error_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Join_Path* attribute of the batch job is set to the value FALSE and the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_ERROR, a batch server that executes a batch job shall perform one of the following actions:

- Set the standard error stream of the session leader of the batch job to the path described by the value of the *Error_Path* attribute of the batch job.
- Buffer the standard error of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Error_Path* attribute of the batch job. Where the batch server buffers standard error is implementation-defined.

Applications shall not rely on having access to the standard error of a batch job prior to the completion of the batch job.

When the *Error_Path* attribute does not specify a host name, then the batch server shall retain the standard error of the batch job on the host of execution.

When the *Error_Path* attribute does specify a host name and the *Keep_Files* attribute does not contain the value KEEP_STD_ERROR, then the final destination of the standard error of the batch job shall be on the host whose host name is specified.

If the path indicated by the value of the *Error_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

When the batch server buffers the standard error of the batch job and the file cannot be opened for write upon completion of the batch job, then the server shall place the standard error in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard error cannot open the standard error path of the batch job for write access, then the batch server shall abort the batch job.

Execution_Time Attribute

A batch server shall not execute a batch job before the time represented by the value of the *Execution_Time* attribute of the batch job. The *Execution_Time* attribute is defined in seconds since the Epoch.

Hold_Types Attribute

A batch server shall support the following hold types:

s Can be set or released by a user with at least a privilege level of batch administrator (SYSTEM).

o Can be set or released by a user with at least a privilege level of batch operator (OPERATOR).

u Can be set or released by the user with at least a privilege level of user, where the user is defined in the *Job_Owner* attribute (USER).

n Indicates that none of the *Hold_Types* attributes are set (NO_HOLD).

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal representation, their behavior, and how they affect the behavior of other utilities.

The value of the *Hold_Types* attribute shall be the union of the valid hold types (**ss**, **oo**, **uu**, and any implementation-defined hold types), or **nn**.

A batch server shall not execute a batch job if the *Hold_Types* attribute of the batch job has a value other than NO_HOLD. If the *Hold_Types* attribute of the batch job has a value other than NO_HOLD, the batch job shall be in the HELD state.

Job_Owner Attribute

The *Job_Owner* attribute consists of a pair of user name and host name values of the form:

```
username@hostname
```

A batch server that accepts a *Queue Batch Job Request* shall set the *Job_Owner* attribute to a string that is the *username@hostname* of the user who submitted the job.

Join_Path Attribute

A batch server that executes a batch job for which the value of the *Join_Path* attribute is TRUE shall ignore the value of the *Error_Path* attribute and merge the standard error of the batch job with the standard output of the batch job.

Keep_Files Attribute

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes the value KEEP_STD_OUTPUT shall retain the standard output of the batch job on the host where execution occurs. The standard output shall be retained in the home directory of the user under whose user ID the batch job is executed and the file name shall be the default file name for the standard output as defined under the **−o** option of the *qsub* utility. The *Output_Path* attribute is not modified.

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes the value KEEP_STD_ERROR shall retain the standard error of the batch job on the host where execution occurs. The standard error shall be retained in the home directory of the user under whose user ID the batch job is executed and the file name shall be the default file name for

standard error as defined under the **–e** option of the *qsub* utility. The *Error_Path* attribute is not modified.

A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes values other than KEEP_STD_OUTPUT and KEEP_STD_ERROR shall retain these other files on the host where execution occurs. These files shall be retained in the home directory of the user under whose user identifier the batch job is executed and the file names shall be the default file names for the files as defined in the conformance document for the implementation.

Mail_Points and Mail_Users Attributes

A batch server that executes a batch job for which one of the values of the *Mail_Points* attribute is the value MAIL_AT_BEGINNING shall send a mail message to each user account listed in the *Mail_Users* attribute of the batch job.

The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.

Output_Path Attribute

The *Output_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_OUTPUT, a batch server that executes a batch job shall either:

- Set the standard output stream of the session leader of the batch job to the destination described by the value of the *Output_Path* attribute of the batch job.

  or:

- Buffer the standard output of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Output_Path* attribute of the batch job.

When the *Output_Path* attribute does not specify a host name, then the batch server shall retain the standard output of the batch job on the host of execution.

When the *Keep_Files* attribute does not contain the value KEEP_STD_OUTPUT and the *Output_Path* attribute does specify a host name, then the final destination of the standard output of the batch job shall be on the host specified.

If the path specified in the *Output_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

Whether or not the batch server buffers the standard output of the batch job until completion of the batch job is implementation-defined. Applications shall not rely on having access to the standard output of a batch job prior to the completion of the batch job.

When the batch server does buffer the standard output of the batch job and the file cannot be opened for write upon completion of the batch job, then the batch server shall place the standard output in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard output cannot open the standard output path of the batch job for write access, then the batch server shall abort the batch job.

Priority Attribute

A batch server implementation may choose to preferentially execute a batch job based on the *Priority* attribute. The interpretation of the batch job *Priority* attribute by a batch server is implementation-defined. If an implementation uses the *Priority* attribute, it shall interpret larger values of the *Priority* attribute to mean the batch job shall be preferentially selected for execution.

Rerunable Attribute

A batch job that began execution but did not complete, because the batch server either shut down or terminated abnormally, shall be requeued if the *Rerunable* attribute of the batch job has the value TRUE.

If a batch job, which was requeued after beginning execution but prior to completion, has a valid checkpoint file and the batch server supports checkpointing, then the batch job shall be restarted from the last valid checkpoint.

If the batch job cannot be restarted from a checkpoint, then when a batch job has a *Rerunable* attribute value of TRUE and was requeued after beginning execution but prior to completion, the batch server shall place the batch job into execution at the beginning of the job.

When a batch job has a *Rerunable* attribute value other than TRUE and was requeued after beginning execution but prior to completion, and the batch job cannot be restarted from a checkpoint, then the batch server shall abort the batch job.

Resource_List Attribute

A batch server that executes a batch job shall establish the resource limits of the session leader of the batch job according to the values of the *Resource_List* attribute of the batch job. Resource limits shall be enforced by an implementation-defined method.

Shell_Path_List Attribute

The *Shell_Path_List* job attribute consists of a list of pairs of path name and host name values. The host name component can be omitted, in which case the path name serves as the default path name when a batch server cannot find the name of the host on which it is running in the list.

A batch server that executes a batch job shall select, from the value of the *Shell_Path_List* attribute of the batch job, a path name where the shell to execute the batch job shall be found. The batch server shall select the path name, in order of preference, according to the following methods:

- Select the path name that contains the name of the host on which the batch server is running.
- Select the path name for which the host name has been omitted.
- Select the path name for the login shell of the user under which the batch job is to execute.

If the shell path value selected is an invalid path name, the batch server shall abort the batch job.

If the value of the selected path name from the *Shell_Path_List* attribute of the batch job represents a partial path, the batch server shall expand the path relative to a path that is implementation-defined.

The batch server that executes the batch job shall execute the program that was selected from the *Shell_Path_List* attribute of the batch job. The batch server shall pass the path to the script of the batch job as the first argument to the shell program.

User_List Attribute

The *User_List* job attribute consists of a list of pairs of user name and host name values. The host name component can be omitted, in which case the user name serves as a default when a batch server cannot find the name of the host on which it is running in the list.

A batch server that executes a batch job shall select, from the value of the *User_List* attribute of the batch job, a user name under which to create the session leader. The server shall select the user name, in order of preference, according to the following methods:

- Select the user name of a value that contains the name of the host on which the batch server executes.
- Select the user name of a value for which the host name has been omitted.
- Select the user name from the *Job_Owner* attribute of the batch job.

Variable_List Attribute

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, each environment variable listed in the *Variable_List* attribute of the batch job, and set the value of each such environment variable to that of the corresponding variable in the variable list.

3.2.2.2 Batch Job Routing

To route a batch job is to select a queue from a list and move the batch job to that queue.

A batch server that has routing queues, which have been started, shall route the jobs in the routing queues owned by the batch server. A batch server is allowed to delay the routing of a batch job. The algorithm for selecting a batch job and the queue to which it will be routed is implementation-defined.

When a routing queue has multiple possible destinations specified, then the precedence of the destination is implementation-defined.

A batch server that routes a batch job to a queue at another server shall move the batch job into the target queue with a *Queue Batch Job Request*.

If the target server rejects the *Queue Batch Job Request*, the routing server shall retry routing the batch job or abort the batch job. A batch server that retries failed routings shall provide a means for the batch administrator to specify the number of retries and the minimum period of time between retries. The means by which an administrator specifies the number of retries and the delay between retries is implementation-defined. When the number of retries specified by the batch administrator has been exhausted, the batch server shall abort the batch job and perform the functions of *Batch Job Exit*; see Section 3.2.2.3.

3.2.2.3 Batch Job Exit

For each job in the EXITING state, the batch server that exited the batch job shall perform the following deferred services in the order specified:

1. If buffering standard error, move that file into the location specified by the *Error_Path* attribute of the batch job.
2. If buffering standard output, move that file into the location specified by the *Output_Path* attribute of the batch job.
3. If the *Mail_Points* attribute of the batch job includes MAIL_AT_EXIT, send mail to the users listed in the *Mail_Users* attribute of the batch job. The mail message shall contain at least

the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.

4. Remove the batch job from the queue.

If a batch server that buffers the standard error output cannot return the standard error file to the standard error path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard error file to the batch job owner.
- Save the standard error file and mail the location and name of the file where the standard error is stored to the batch job owner.
- Save the standard error file and notify the user by other means, in which case the conformance document for the implementation shall document the method of notification.

If a batch server that buffers the standard output cannot return the standard output file to the standard output path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard output file to the batch job owner.
- Save the standard output file and mail the location and name of the file where the standard output is stored to the batch job owner.
- Save the standard output file and notify the user by other means, in which case the conformance document for the implementation shall document the method of notification.

At the conclusion of job exit processing, the batch job is no longer managed by a batch server.

3.2.2.4 Batch Server Restart

A batch server that has been either shutdown or terminated abnormally, and has returned to operation, is said to have *restarted*.

Upon restarting, a batch server shall requeue those jobs managed by the batch server that were in the RUNNING state at the time the batch server shut down and for which the *Rerunable* attribute of the batch job has the value TRUE.

Queues are defined to be non-volatile. A batch server shall store the content of queues that it controls in such a way that server and system shutdowns do not erase the content of the queues.

3.2.2.5 Batch Job Abort

A batch server that cannot perform a deferred service for a batch job shall abort the batch job.

A batch server that aborts a batch job shall perform the following services:

- Delete the batch job from the queue in which it resides.
- If the *Mail_Points* attribute of the batch job includes the value MAIL_AT_ABORT, send mail to the users listed in the value of the *Mail_Users* attribute of the job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, the *Job_Owner* attribute, and the reason for the abort.
- If the batch job was in the RUNNING state, terminate the session leader of the executing job by sending the session leader a SIGKILL, place the batch job in the EXITING state, and perform the services of *Batch Job Exit*.

3.2.3 Requested Batch Services

This section describes the services provided by batch servers in response to requests from clients. Table 3-5 summarizes the current set of batch service requests and for each gives its type (deferred or not) and whether it is an optional function.

Table 3-5 Batch Services Summary

Batch Service	Deferred	Optional
Batch Job Execution	Yes	No
Batch Job Routing	Yes	No
Batch Job Exit	Yes	No
Batch Server Restart	Yes	No
Batch Job Abort	Yes	No
Delete Batch Job Request	No	No
Hold Batch Job Request	No	No
Batch Job Message Request	No	Yes
Batch Job Status Request	No	No
Locate Batch Job Request	No	Yes
Modify Batch Job Request	No	No
Move Batch Job Request	No	No
Queue Batch Job Request	No	No
Batch Queue Status Request	No	No
Release Batch Job Request	No	No
Rerun Batch Job Request	No	No
Select Batch Jobs Request	No	No
Server Shutdown Request	No	No
Server Status Request	No	No
Signal Batch Job Request	No	No
Track Batch Job Request	No	Yes

If a request is rejected because the batch client is not authorized to perform the action, the batch server shall return the same status as when the batch job does not exist.

3.2.3.1 Delete Batch Job Request

A batch job is defined to have been deleted when it has been removed from the queue in which it resides and not instantiated in another queue. A client requests that the server that manages a batch job delete the batch job. Such a request is called a *Delete Batch Job Request*.

A batch server shall reject a *Delete Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to delete the designated job.
- The designated job is not managed by the batch server.
- The designated job is in a state inconsistent with the delete request.

A batch server may reject a *Delete Batch Job Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Delete Batch Job Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server requested to delete a batch job shall delete the batch job if the batch job exists and is not in the EXITING state.

A batch server that deletes a batch job in the RUNNING state shall send a SIGKILL signal to the session leader of the batch job. A batch server may send additional signals to the session leader of the job prior to sending the SIGKILL signal. The conformance document for such a batch server shall document the signals that are sent to the session leader.

A batch server that deletes a batch job in the RUNNING state shall place the batch job in the EXITING state after it has killed the session leader of the batch job and shall perform the services of batch job exit.

3.2.3.2 Hold Batch Job Request

A batch client can request that the batch server add one or more holds to a batch job. Such a request is called a *Hold Batch Job Request*.

A batch server shall reject a *Hold Batch Job Request* if any of the following statements are true:

- The batch server does not support one or more of the requested holds to be added to the batch job.
- The user of the batch client is not authorized to add one or more of the requested holds to the batch job.
- The batch server does not manage the specified job.
- The designated job is in the EXITING state.

A batch server may reject a *Hold Batch Job Request* for other reasons. The conformance document for an implementation shall document the reasons for which a *Hold Batch Job Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Hold Batch Job Request* for a batch job in the RUNNING state shall place a hold on the batch job. The conformance document shall describe what effect, if any, the hold will have on a batch job in the RUNNING state.

A batch server that accepts a *Hold Batch Job Request* shall add each type of hold listed in the *Hold Batch Job Request*, that is not already present, to the value of the *Hold_Types* attribute of the batch job.

3.2.3.3 Batch Job Message Request

Batch Job Message Request is an optional feature of batch servers. If an implementation supports *Batch Job Message Request*, the statements in this section apply and the configuration variable POSIX2_PBS_MESSAGE shall be set to 1.

A batch client can request that a batch server write a message into certain output files of a batch job. Such a request is called a *Batch Job Message Request*.

A batch server shall reject a *Batch Job Message Request* if any of the following statements are true:

- The batch server does not support sending messages to jobs.
- The user of the batch client is not authorized to post a message to the designated job.
- The designated job does not exist on the batch server.
- The designated job is not in the RUNNING state.

A batch server may reject a *Batch Job Message Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Batch Job Message Request* may be rejected. The conformance document for an implementation shall describe the method

used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Batch Job Message Request* shall write the message sent by the batch client into the files indicated by the batch client.

3.2.3.4 Batch Job Status Request

A batch client can request that a batch server respond with the status and attributes of a batch job. Such a request is called a *Batch Job Status Request*.

A batch server shall reject a *Batch Job Status Request* if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated job.
- The designated job is not managed by the batch server.

A batch server may reject a *Batch Job Status Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Batch Job Status Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Batch Job Status Request* shall return a *Batch Job Status Message* to the batch client.

A batch server may return other information in response to a *Batch Job Status Request*.

3.2.3.5 Locate Batch Job Request

Locate Batch Job Request is an optional feature of batch servers. If an implementation supports *Locate Batch Job Request*, the statements in this section apply and the configuration variable POSIX2_PBS_LOCATE shall be set to 1.

A batch client can ask a batch server to respond with the location of a batch job that was created by the batch server. Such a request is called a *Locate Batch Job Request*.

A batch server that accepts a *Locate Batch Job Request* shall return a *Batch Job Location Message* to the batch client.

A batch server may reject a *Locate Batch Job Request* for a batch job that was not created by that server.

A batch server may reject a *Locate Batch Job Request* for a batch job that is no longer managed by that server; that is, for a batch job that is not in a queue owned by that server.

A batch server may reject a *Locate Batch Job Request* for other reasons. The conformance document for an implementation shall document the reasons for which a *Locate Batch Job Request* may be rejected.

3.2.3.6 Modify Batch Job Request

Batch clients modify (alter) the attributes of a batch job by making a request to the server that manages the batch job. Such a request is called a *Modify Batch Job Request*.

A batch server shall reject a *Modify Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to make the requested modification to the batch job.
- The designated job is not managed by the batch server.
- The requested modification is inconsistent with the state of the batch job.

- An unrecognized resource is requested for a batch job in an execution queue.

A batch server may reject a *Modify Batch Job Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Modify Batch Job Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Modify Batch Job Request* shall modify all the specified attributes of the batch job. A batch server that rejects a *Modify Batch Job Request* shall modify none of the attributes of the batch job.

If the servicing by a batch server of an otherwise valid request would result in no change, then the batch server shall indicate successful completion of the request.

3.2.3.7 Move Batch Job Request

A batch client can request that a batch server move a batch job to another destination. Such a request is called a *Move Batch Job Request*.

A batch server shall reject a *Move Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove the designated job from the queue in which the batch job resides.
- The user of the batch client is not authorized to move the designated job to the destination.
- The designated job is not managed by the batch server.
- The designated job is in the EXITING state.
- The destination is inaccessible.

A batch server can reject a *Move Batch Job Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Move Batch Job Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Move Batch Job Request* shall perform the following services:

- Queue the designated job at the destination.
- Remove the designated job from the queue in which the batch job resides.

If the destination resides on another batch server, the batch server shall queue the batch job at the destination by sending a *Queue Batch Job Request* to the other server. If the *Queue Batch Job Request* fails, the batch server shall reject the *Move Batch Job Request*. If the *Queue Batch Job Request* succeeds, the batch server shall remove the batch job from its queue.

The batch server shall not modify any attributes of the batch job.

3.2.3.8 Queue Batch Job Request

A batch queue is controlled by one and only one batch server. A batch server is said to own the queues that it controls. Batch clients make requests of batch servers to have jobs queued. Such a request is called a *Queue Batch Job Request*.

A batch server requested to queue a batch job for which the queue is unspecified shall select a queue for the batch job. Such a queue is called the *default queue* of the batch server. The conformance document for the implementation shall document the means by which the batch server determines the default queue. The implementation shall provide the means for a batch administrator to specify the default queue. The queue, whether specified or defaulted, is called

the *target queue.*

A batch server shall reject a *Queue Batch Job Request* if any of the following statements are true:

- The client is not authorized to create a batch job in the target queue.
- The request specifies a queue that does not exist on the batch server.
- The target queue is an execution queue and the batch server cannot satisfy a resource requirement of the batch job.
- The target queue is an execution queue and an unrecognized resource is requested.
- The target queue is an execution queue, the batch server does not support checkpointing, and the value of the *Checkpoint* attribute of the batch job is not NO_CHECKPOINT.
- The job requires access to a user identifier that the batch client is not authorized to access.

A batch server may reject a *Queue Batch Job Request* for other reasons. The conformance document for an implementation shall document the reasons for which a *Queue Batch Job Request* may be rejected.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_O_QUEUE value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the name of the target queue. Once set, no server shall change the value of PBS_O_QUEUE, even if the batch job is moved to another queue.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBID value is missing from the value of the *Variable_List* attribute shall add that variable to the list and set the value to the batch job identifier assigned by the server in the format:

```
sequence_number.server
```

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBNAME value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the *Job_Name* attribute of the batch job.

3.2.3.9 Batch Queue Status Request

A batch client can request that a batch server respond with the status and attributes of a queue. Such a request is called a *Batch Queue Status Request*.

A batch server shall reject a *Batch Queue Status Request* if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated queue.
- The designated queue does not exist on the batch server.

A batch server may reject a *Batch Queue Status Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Batch Queue Status Request* is rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Batch Queue Status Request* shall return a *Batch Queue Status Reply* to the batch client.

4455 *3.2.3.10 Release Batch Job Request*

4456 A batch client can request that server remove one or more holds from a batch job. Such a request
4457 is called a *Release Batch Job Request*.

4458 A batch server shall reject a *Release Batch Job Request* if any of the following statements are true:

4459 • The user of the batch client is not authorized to remove one or more of the requested holds
4460 from the batch job.

4461 • The batch server does not manage the specified job.

4462 A batch server may reject a *Release Batch Job Request* for other reasons. The conformance
4463 document for an implementation shall document the reasons for which a *Release Batch Job*
4464 *Request* may be rejected. The conformance document for an implementation shall describe the
4465 method used to determine whether the user of a client is authorized to perform the requested
4466 action.

4467 A batch server that accepts a *Release Batch Job Request* shall remove each type of hold listed in the
4468 *Release Batch Job Request*, that is present, from the value of the *Hold_Types* attribute of the batch
4469 job.

4470 *3.2.3.11 Rerun Batch Job Request*

4471 To rerun a batch job is to kill the session leader of the batch job and leave the batch job eligible
4472 for re-execution. A batch client can request that a batch server rerun a batch job. Such a request is
4473 called *Rerun Batch Job Request*.

4474 A batch server shall reject a *Rerun Batch Job Request* if any of the following statements are true:

4475 • The user of the batch client is not authorized to rerun the designated job.

4476 • The *Rerunable* attribute of the designated job has the value FALSE.

4477 • The designated job is not in the RUNNING state.

4478 • The batch server does not manage the designated job.

4479 A batch server may reject a *Rerun Batch Job Request* for other reasons. The conformance document
4480 for an implementation shall describe the reasons for which a *Rerun Batch Job Request* may be
4481 rejected. The conformance document for an implementation shall describe the method used to
4482 determine whether the user of a client is authorized to perform the requested action.

4483 A batch server that rejects a *Rerun Batch Job Request* shall in no way modify the execution of the
4484 batch job.

4485 A batch server that accepts a request to rerun a batch job shall perform the following services:

4486 • Requeue the batch job in the execution queue in which it was executing.

4487 • Send a SIGKILL signal to the process group of the session leader of the batch job.

4488 An implementation may indicate to the batch job owner that the batch job has been rerun. The
4489 conformance document for an implementation shall state whether the batch job owner is
4490 notified that a batch job is rerun, and if so, shall describe the means used.

4491 A batch server that reruns a batch job may send other signals to the session leader of the batch
4492 job prior to sending the SIGKILL signal. The conformance document for an implementation
4493 shall describe any other signals that may be sent.

4494 A batch server may preferentially select a rerun job for execution. The conformance document
4495 for an implementation shall state whether rerun jobs shall be selected for execution before other

jobs.

3.2.3.12 Select Batch Jobs Request

A batch client can request from a batch server a list of jobs managed by that server that match a list of selection criteria. Such a request is called a *Select Batch Jobs Request*. All the batch jobs managed by the batch server that receives the request are candidates for selection.

A batch server that accepts a *Select Batch Jobs Request* shall return a list of zero or more job identifiers that correspond to jobs that meet the selection criteria.

If the batch client is not authorized to query the status of a batch job, the batch server shall not select the batch job.

3.2.3.13 Server Shutdown Request

A batch server is defined to have shut down when it does not respond to requests from clients and does not perform deferred services for jobs. A batch client can request that a batch server shut down. Such a request is called a *Server Shutdown Request*.

A batch server shall reject a *Server Shutdown Request* from a client that is not authorized to shut down the batch server. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server may reject a *Server Shutdown Request* for other reasons. The conformance document for an implementation shall document the reasons for which a *Server Shutdown Request* may be rejected.

At server shutdown, a batch server shall do, in order of preference, one of the following:

- If checkpointing is implemented and the batch job is checkpointable, then checkpoint the batch job and requeue it.
- If the batch job is rerunable, then requeue the batch job to be rerun (restarted from the beginning).
- Abort the batch job.

3.2.3.14 Server Status Request

A batch client can request that a batch server respond with the status and attributes of the batch server. Such a request is called a *Server Status Request*.

A batch server shall reject a *Server Status Request* if the following statement is true:

- The user of the batch client is not authorized to query the status of the designated server.

A batch server may reject a *Server Status Request* for other reasons. The conformance document for an implementation shall describe the reasons for which a *Server Status Request* may be rejected. The conformance document for an implementation shall describe the method used to determine whether the user of a client is authorized to perform the requested action.

A batch server that accepts a *Server Status Request* shall return a *Server Status Reply* to the batch client.

4533 *3.2.3.15 Signal Batch Job Request*

4534 A batch client can request that a batch server signal the session leader of a batch job. Such a
4535 request is called a *Signal Batch Job Request*.

4536 A batch server shall reject a *Signal Batch Job Request* if any of the following statements are true:

4537 • The user of the batch client is not authorized to signal the batch job.

4538 • The job is not in the RUNNING state.

4539 • The batch server does not manage the designated job.

4540 • The requested signal is not supported by the implementation.

4541 A batch server may reject a *Signal Batch Job Request* for other reasons. The conformance
4542 document for an implementation shall describe the reasons for which a *Signal Batch Job Request*
4543 may be rejected. The conformance document for an implementation shall describe the method
4544 used to determine whether the user of a client is authorized to perform the requested action.

4545 A batch server that accepts a request to signal a batch job shall send the signal requested by the
4546 batch client to the process group of the session leader of the batch job.

4547 *3.2.3.16 Track Batch Job Request*

4548 *Track Batch Job Request* is an optional feature of batch servers. If an implementation supports
4549 *Track Batch Job Request*, the statements in this section apply and the configuration variable
4550 POSIX2_PBS_TRACK shall be set to 1.

4551 *Track Batch Job Request* provides a method for tracking the current location of a batch job. Clients
4552 may use the tracking information to determine the batch server that should receive a batch
4553 server request.

4554 If *Track Batch Job Request* is supported by a batch server, then when the batch server queues a
4555 batch job as a result of a *Queue Batch Job Request*, and the batch server is not the batch server that
4556 created the batch job, the batch server shall send a *Track Batch Job Request* to the batch server that
4557 created the job.

4558 If *Track Batch Job Request* is supported by a batch server, then the *Track Batch Job Request* may also
4559 be sent to other servers as a backup to the primary server. The method by which backup servers
4560 are specified is implementation-defined.

4561 If *Track Batch Job Request* is supported by a batch server that receives a *Track Batch Job Request*,
4562 then the batch server shall record the current location of the batch job as contained in the
4563 request.

3.3 Common Behavior for Batch Environment Utilities

3.3.1 Batch Job Identifier

A utility shall recognize *job_identifier*s of the format:

```
[sequence_number][.server_name][@server]
```

where:

sequence_number An integer that, when combined with *server_name*, provides a batch job identifier that is unique within the batch system.

server_name The name of the batch server to which the batch job was originally submitted.

server The name of the batch server that is currently managing the batch job.

If the application omits the batch *server_name* portion of a batch job identifier, a utility shall use the name of a default batch server.

If the application omits the batch *server* portion of a batch job identifier, a utility shall use:

- The batch server indicated by *server_name*, if present.
- The name of the default batch server.
- The name of the batch server that is currently managing the batch job.

If only *@server* is specified, then the status of all jobs owned by the user on the requested server is listed.

The means by which a utility determines the default batch server is implementation-defined.

If the application presents the batch *server* portion of a batch job identifier to a utility, the utility shall send the request to the specified server.

A strictly conforming application shall use the syntax described for the job identifier. Whenever a batch job identifier is specified whose syntax is not recognized by an implementation, then a message for each error that occurs shall be written to standard error and the utility shall exit with an exit status greater than zero.

When a batch job identifier is supplied as an argument to a batch utility and the *server_name* portion of the batch job identifier is omitted, then the utility shall use the name of the default batch server.

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is omitted, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is specified, then the utility shall send the required *Batch Server Request* to the specified server.

3.3.2 Destination

The utility shall recognize a *destination* of the format:

```
[queue][@server]
```

where:

queue The name of a valid execution or routing queue at the batch server denoted by *@server*, defined as a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.

server The name of a batch server, defined as a string of alphanumeric characters in the portable character set.

If the application omits the batch *server* portion of a destination, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

The means by which a utility determines the default batch server is implementation-defined.

If the application omits the *queue* portion of a destination, then the utility shall use the name of the default queue at the batch server chosen.

The means by which a batch server determines its default queue is implementation-defined.

If a destination is specified in the *queue@server* form, then the utility shall use the specified queue at the specified server.

A strictly conforming application shall use the syntax described for a destination. Whenever a destination is specified whose syntax is not recognized by an implementation, then a message shall be written to standard error and the utility shall exit with an exit status greater than zero.

3.3.3 Multiple Keyword-Value Pairs

For each option that can have multiple keyword-value pair arguments, the following rules shall apply. Examples of options that can have list-oriented option-arguments are **–u** *value@keyword* and **–l** *keyword=value*.

1. If a batch utility is presented with a list-oriented option-argument for which a keyword has a corresponding value that begins with a single or double quote, then the utility shall stop interpreting the input stream for delimiters until a second single or double quote, respectively, is encountered. This feature allows some flexibility for a comma (`','`) or equals sign (`'='`) to be part of the value string for a particular keyword; for example:

   ```
   keywd1='val1,val2',keywd2="val3,val4"
   ```

   Note: This may require the user to escape the quotes as in the following command:

   ```
   foo –xkeywd1=\'val1,val2\',keywd2=\"val3,val4\"
   ```

2. If a batch server is presented with a list-oriented attribute that has a keyword that was encountered earlier in the list, then the later entry for that keyword shall replace the earlier entry.

3. If a batch server is presented with a list-oriented attribute that has a keyword without any corresponding value of the form *keyword=* or *@keyword* and the same keyword was encountered earlier in the list, then the prior entry for that keyword shall be ignored by the

batch server.

4. If a batch utility is expecting a list-oriented option-argument entry of the form *keyword*=*value*, but is presented with an entry of the form *keyword* without any corresponding *value*, then the entry shall be treated as though a default value of NULL was assigned (that is, *keyword*=NULL) for entry parsing purposes. The utility shall include only the keyword, not the NULL value, in the associated job attribute.

5. If a batch utility is expecting a list-oriented option-argument entry of the form *value*@*keyword*, but is presented with an entry of the form *value* without any corresponding *keyword*, then the entry shall be treated as though a keyword of NULL was assigned (that is, *value*@NULL) for entry parsing purposes. The utility shall include only the value, not the NULL keyword, in the associated job attribute.

6. A batch server shall accept a list-oriented attribute that has multiple occurrences of the same keyword, interpreting the keywords, in order, with the last value encountered taking precedence over prior instances of the same keyword. This rule allows, but does not require, a batch utility to preprocess the attribute to remove duplicate keywords.

7. If a batch utility is presented with multiple list-oriented option-arguments on the command line or in script directives, or both, for a single option, then the utility shall concatenate, in order, any command line keyword and value pairs to the end of any directive keyword and value pairs separated by a single comma to produce a single string that is an equivalent, valid option-argument. The resulting string shall be assigned to the associated attribute of the batch job (after optionally removing duplicate entries as described in item 6.

Chapter 4
Utilities

This chapter contains the definitions of the utilities, as follows:

- Mandatory utilities that are present on every conformant system
- Optional utilities that are present only on systems supporting the associated option; see Section 1.8.1 (on page 2212) for information on the options in this volume of IEEE Std. 1003.1-200x

NAME

admin — create and administer SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI

```
admin –i[name][–n][–a login][–d flag][–f flag][–m mrlist][–r rel]
    [–t[name][–y[comment]] newfile

admin –n[–a login][–d flag][–f flag][–m mrlist][–t[name]][–y[comment]]
    newfile ...

admin [–a login][–d flag][–m mrlist][–r rel][–t[name]] file ...

admin –h file ...

admin –z file ...
```

DESCRIPTION

The *admin* utility shall create new SCCS files or change parameters of existing ones. If a named file does not exist, it shall be created, and its parameters shall be initialized according to the specified options. Parameters not initialized by an option shall be assigned a default value. If a named file does exist, parameters corresponding to specified options shall be changed, and other parameters shall be left as is.

All SCCS file names supplied by the application shall be of the form s.*filename*. New SCCS files shall be given read-only permission mode. Write permission in the parent directory is required to create a file. All writing done by *admin* shall be to a temporary *x-file*, named x.*filename* (see *get*) created with read-only mode if *admin* is creating a new SCCS file, or created with the same mode as that of the SCCS file if the file already exists. After successful execution of *admin*, the SCCS file shall be removed (if it exists), and the *x-file* shall be renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occur.

The *admin* utility shall also use a transient lock file (named z.*filename*), which is used to prevent simultaneous updates to the SCCS file; see *get* (on page 2685).

OPTIONS

The *admin* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the **–i**, **–t**, and **–y** options have optional option-arguments. These optional option-arguments shall not be presented as separate arguments. The following options are supported:

–n Create a new SCCS file. When **–n** is used without **–i**, the SCCS file shall be created with control information but without any file data.

–i[*name***]** Specify the *name* of a file from which the text for a new SCCS file shall be taken. The text constitutes the first delta of the file (see the **–r** option for delta numbering scheme). If the **–i** option is used, but the *name* option-argument is omitted, the text shall be obtained by reading the standard input. If this option is omitted, the SCCS file shall be created with control information but without any file data. The **–i** option implies the **–n** option.

–r *rel* Specify the *rel*ease into which the initial delta is inserted. If the **–r** option is not used, the initial delta shall be inserted into release 1. The level of the initial delta shall always be 1 (by default, initial deltas are named 1.1).

–t[*name***]** Specify the *name* of a file from which descriptive text for the SCCS file shall be taken. In the case of existing SCCS files (neither **–i** nor **–n** is specified):

- A **–t** option without a *name* option-argument shall cause the removal of descriptive text (if any) currently in the SCCS file.
- A **–t** option with a *name* option-argument shall cause the text (if any) in the named file to replace the descriptive text (if any) currently in the SCCS file.

–f *flag* Specify a *flag*, and, possibly, a value for the *flag*, to be placed in the SCCS file. Several **–f** options may be supplied on a single *admin* command line. The allowable flags and their values are:

b Allow use of the **–b** option on a *get* command to create branch deltas.

c*ceil* Specify the highest release (that is, ceiling), a number less than or equal to 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **c** flag shall be 9 999.

f*floor* Specify the lowest release (that is, floor), a number greater than 0 but less than 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **f** flag shall be 1.

d*SID* Specify the default delta number (SID) to be used by a *get* command.

i*str* Treat the ''No ID keywords'' message issued by *get* or *delta* as a fatal error. In the absence of this flag, the message is only a warning. The message is issued if no SCCS identification keywords (see *get* (on page 2685)) are found in the text retrieved or stored in the SCCS file. If a value is supplied, the application shall ensure that the keywords exactly match the given string; however, the string shall contain a keyword, and no embedded <newline>s.

j Allow concurrent *get* commands for editing on the same SID of an SCCS file. This allows multiple concurrent updates to the same version of the SCCS file.

l*list* Specify a *list* of releases to which deltas can no longer be made (that is, *get* **–e** against one of these locked releases fails). The *list* has the following syntax:

```
<list> ::= a | <range-list>
<range-list> ::= <range> | <range-list>, <range>
```

The character *a* in the *list* shall be equivalent to specifying all releases for the named SCCS file.

n Cause *delta* to create a null delta in each of those releases (if any) being skipped when a delta is made in a new release (for example, in making delta 5.1 after delta 2.7, releases 3 and 4 are skipped). These null deltas serve as anchor points so that branch deltas may later be created from them. The absence of this flag shall cause skipped releases to be nonexistent in the SCCS file, preventing branch deltas from being created from them in the future.

q*text* Substitute user-definable *text* for all occurrences of the %**Q**% keyword in the SCCS file text retrieved by *get*.

m*mod* Specify the module name of the SCCS file substituted for all occurrences of the %**M**% keyword in the SCCS file text retrieved by *get*. If the **m** flag is not specified, the value assigned shall be the name of the SCCS file with the leading `'.'` removed.

t*type* Specify the *type* of module in the SCCS file substituted for all occurrences of the %**Y**% keyword in the SCCS file text retrieved by *get*.

v*pgm* Cause *delta* to prompt for modification request (MR) numbers as the reason for creating a delta. The optional value specifies the name of an MR number validation program. (If this flag is set when creating an SCCS file, the application shall ensure that the **m** option is also used even if its value is null.)

–**d** *flag* Remove (delete) the specified *flag* from an SCCS file. Several –**d** options may be supplied on a single *admin* command. See the –**f** option for allowable *flag* names. (The **l***list* flag gives a *list* of releases to be unlocked. See the –**f** option for further description of the **l** flag and the syntax of a *list*.)

–**a** *login* Specify a *login* name, or numerical group ID, to be added to the list of users who may make deltas (changes) to the SCCS file. A group ID is equivalent to specifying all *login* names common to that group ID. Several –**a** options may be used on a single *admin* command line. As many *login*s, or numerical group IDs, as desired may be on the list simultaneously. If the list of users is empty, then anyone may add deltas. If *login* or group ID is preceded by a `'!'`, the users so specified are denied permission to make deltas.

–**e** *login* Specify a *login* name, or numerical group ID, to be erased from the list of users allowed to make deltas (changes) to the SCCS file. Specifying a group ID is equivalent to specifying all *login* names common to that group ID. Several –**e** options may be used on a single *admin* command line.

–**y[***comment***]** Insert the *comment* text into the SCCS file as a comment for the initial delta in a manner identical to that of *delta*. In the POSIX locale, omission of the –**y** option results in a default comment line being inserted in the form:

`"date and time created %s %s by %s", <`*date*`>, <`*time*`>, <`*login*`>`

where <*date*> is expressed in the *date* utility's %*y*/%*m*/%*d* format, <*time*> in the *date* utility's %*T* format, and <*login*> is the login name of the user creating the file.

–**m** *mrlist* Insert the list of modification request (MR) numbers into the SCCS file as the reason for creating the initial delta in a manner identical to *delta*. The application shall ensure that the **v** flag is set and the MR numbers are validated if the **v** flag has a value (the name of an MR number validation program). Diagnostics occur if the **v** flag is not set or MR validation fails.

–**h** Check the structure of the SCCS file and compare the newly computed checksum (the sum of all the characters in the SCCS file except those in the first line) with the checksum that is stored in the first line of the SCCS file. Appropriate error diagnostics are produced.

–**z** Recompute the SCCS file checksum and store it in the first line of the SCCS file (see the –**h** option above). Note that use of this option on a truly corrupted file may prevent future detection of the corruption.

OPERANDS

The following operands shall be supported:

file A path name of an existing SCCS file or a directory. If *file* is a directory, the *admin* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s.**) and unreadable files shall be silently ignored.

newfile A path name of an SCCS file to be created.

If a single instance of *file* or *newfile* is specified as '−', the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only if the **−i** is specified without an option-argument or if a *file* or *newfile* operand is specified as '−'. If the first character of any standard input line is SOH (binary 001), the results are unspecified.

INPUT FILES

The existing SCCS files are text files of an unspecified format. The file named by the **−i** option's *name* option-argument is a text file; if the first character of any line in this file is SOH (binary 001), the results are unspecified.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *admin*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and the contents of the default **−y** comment.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

Any SCCS files created shall be text files of an unspecified format. During processing of a *file*, a locking *z-file*, as described in *get* (on page 2685), may be created and deleted.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

It is recommended that directories containing SCCS files be writable by the owner only, and that SCCS files themselves be read-only. The mode of the directories should allow only the owner to modify SCCS files contained in the directories. The mode of the SCCS files prevents any modification at all except by SCCS commands.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Conformance to Utility Syntax Guidelines mandated, with exceptions as noted.

Internationalized environment variable support mandated.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements.

The grammar is updated.

NAME

alias — define or display aliases

SYNOPSIS

UP

```
alias [alias-name[=string] ...]
```

DESCRIPTION

The *alias* utility shall create or redefine alias definitions or write the values of existing alias definitions to standard output. An alias definition provides a string value that shall replace a command name when it is encountered; see Section 2.3.1 (on page 2239).

An alias definition shall affect the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this volume of IEEE Std. 1003.1-200x, the alias definition shall not affect the parent process of the current shell nor any utility environment invoked by the shell; see Section 2.13 (on page 2273).

OPTIONS

None.

OPERANDS

The following operands shall be supported:

alias-name Write the alias definition to standard output.

alias-name=string
Assign the value of *string* to the alias *alias-name*.

If no operands are given, all alias definitions shall be written to standard output.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *alias*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The format for displaying aliases (when no operands or only *name* operands are specified) shall be:

```
"%s=%s\n", name, value
```

The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the shell. See the description of shell quoting in Section 2.2 (on page 2236).

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 One of the *name* operands specified did not have an alias definition, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Change *ls* to give a columnated, more annotated output:

   ```
   alias ls="ls –CF"
   ```

2. Create a simple ‘‘redo’’ command to repeat previous entries in the command history file:

   ```
   alias r='fc –s'
   ```

3. Use 1K units for *du*:

   ```
   alias du=du\ –k
   ```

4. Set up *nohup* so that it can deal with an argument that is itself an alias name:

   ```
   alias nohup="nohup "
   ```

RATIONALE

The *alias* description is based on historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std. 1003.1-200x, such as command line editing.

Since *alias* affects the current shell execution environment, it is generally provided as a shell regular built-in.

Historical versions of the KornShell have allowed aliases to be exported to scripts that are invoked by the same shell. This is triggered by the *alias* **–x** flag; it is allowed by this volume of IEEE Std. 1003.1-200x only when an explicit extension such as **–x** is used. The standard developers considered that aliases were of use primarily to interactive users and that they

should normally not affect shell scripts called by those users; functions are available to such scripts.

Historical versions of the KornShell had not written aliases in a quoted manner suitable for reentry to the shell, but this volume of IEEE Std. 1003.1-200x has made this a requirement for all similar output. Therefore, consistency with this volume of IEEE Std. 1003.1-200x was chosen over this detail of historical practice.

FUTURE DIRECTIONS

None.

Section 2.9.5 (on page 2263)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

NAME

ar — create and maintain library archives

SYNOPSIS

SD `ar –d[–v] archive file ...`

XSI `ar –m[–abiv][posname] archive file ...`

XSI `ar –p[–v][–s]archive [file ...]`

XSI `ar –q[–cv] archive file ...`

XSI `ar –r[–cuv][–abi][posname]archive file ...`

XSI `ar –t[–v][–s]archive [file ...]`

XSI `ar –x[–v][–sCT]archive [file ...]`

DESCRIPTION

The *ar* utility can be used to create and maintain groups of files combined into an archive. Once an archive has been created, new files can be added, and existing files can be extracted, deleted, or replaced. When an archive consists entirely of valid object files, the implementation shall format the archive so that it is usable as a library for link editing (see *c99*, *cc*, and *fort77*). When some of the archived files are not valid object files, the suitability of the archive for library use is undefined. If an archive file consists entirely of printable files, the entire archive file is printable.

When *ar* creates an archive file, it creates administrative information indicating whether a symbol table is present in the archive. When there is at least one object file that *ar* recognizes as such in the archive, an archive symbol table is created in the archive file and maintained by *ar*; it is used by the link editor to search the archive file. Whenever the *ar* utility is used to create or update the contents of such an archive, the symbol table is rebuilt. The **–s** option forces the symbol table to be rebuilt.

All *file* operands can be path names. However, files within archives shall be named by a file name, which is the last component of the path name used when the file was entered into the archive. The comparison of *file* operands to the names of files in archives shall be performed by comparing the last component of the operand to the name of the archive file.

It is unspecified whether multiple files in the archive may be identically named. In the case of such files, however, each *file* and *posname* operand shall match only the first archive file having a name that is the same as the last component of the operand.

OPTIONS

The *ar* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

XSI **–a** Position new files in the archive after the file named by the *posname* operand.

XSI **–b** Position new files in the archive before the file named by the *posname* operand.

–c Suppress the diagnostic message that is written to standard error by default when the archive file *archive* is created.

XSI **–C** Prevent extracted files from replacing like-named files in the file system. This option is useful when **–T** is also used, to prevent truncated file names from replacing files with the same prefix.

–d Delete one or more *file*s from *archive*.

XSI **–i** Position new files in the archive before the file named by the *posname* operand (equivalent to **–b**).

XSI **–m** Move the named files. The **–a**, **–b**, or **–i** options with the *posname* operand indicate the position; otherwise, move the files to the end of the archive.

–p Write the contents of the *file*s from *archive* to the standard output. If no *file*s are specified, the contents of all files in the archive shall be written in the order of the archive.

XSI **–q** Quickly append the named files to the end of the archive file. In this case *ar* does not check whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece by piece.

–r Replace or add *file*s to *archive*. If the archive named by *archive* does not exist, a new archive file shall be created and a diagnostic message shall be written to standard error (unless the **–c** option is specified). If no *file*s are specified and the *archive* exists, the results are undefined. Files that replace existing files shall not change the order of the archive. Files that do not replace existing files shall be
XSI appended to the archive unless a **–a**, **–b**, or **–i** option specifies another position.

XSI **–s** Force the regeneration of the archive symbol table even if *ar* is not invoked with an option that modifies the archive file contents. This option is useful to restore the archive symbol table after it has been stripped; see *strip*.

–t Write a table of contents of *archive* to the standard output. The files specified by the *file* operands shall be included in the written list. If no *file* operands are specified, all files in *archive* shall be included in the order of the archive.

XSI **–T** Allow file name truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long is an error; a diagnostic message is written and the file is not extracted.

–u Update older files. When used with the **–r** option, files within the archive are replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file within the archive.

–v Give verbose output. When used with the option characters **–d**, **–r**, or **–x**, write a detailed file-by-file description of the archive creation and maintenance activity, as described in the STDOUT section.

When used with **–p**, write the name of the file to the standard output before writing the file itself to the standard output, as described in the STDOUT section.

When used with **–t**, include a long listing of information about the files within the archive, as described in the STDOUT section.

–x Extract the files named by the *file* operands from *archive*. The contents of the archive file shall not be changed. If no *file* operands are given, all files in the archive shall be extracted. The modification time of each file extracted shall be set to the time the file is extracted from the archive.

OPERANDS

The following operands shall be supported:

archive A path name of the archive file.

file A path name. Only the last component shall be used when comparing against the names of files in the archive. If two or more *file* operands have the same last path name component (basename), the results are unspecified. The implementation's archive format shall not truncate valid file names of files added to or replaced in the archive.

XSI *posname* The name of a file in the archive file, used for relative positioning; see options **–m** and **–r**.

STDIN

Not used.

INPUT FILES

The input file named by *archive* shall be a file in the format created by *ar* **–r**.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ar*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and content for date and time strings written by *ar* **–tv**.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the path name that overrides the default directory for temporary files, if any.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **–d** option is used with the **–v** option, the standard output format shall be:

`"d – %s\n", <`*file*`>`

where *file* is the operand specified on the command line.

If the **–p** option is used with the **–v** option, *ar* shall precede the contents of each file with:

`"\n<%s>\n\n", <`*file*`>`

where *file* is the operand specified on the command line, if *file* operands were specified, and the name of the file in the archive if they were not.

If the **–r** option is used with the **–v** option:

- If *file* is already in the archive, the standard output format shall be:

  `"r – %s\n", <file>`

  where <*file*> is the operand specified on the command line.

- If *file* is not already in the archive, the standard output format shall be:

  `"a – %s\n", <file>`

  where <*file*> is the operand specified on the command line.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 48 suggests changing the above to "where <file> is the member name found to be in conflict". If the command line contains a path name which is not a simple file name (that is, contains a slash), does it print the member name (which seems what's intended) or the actual text from the command line (which is what's said)? This will eventually need to be an interpretation against .2b.

If the **–t** option is used, *ar* shall write the names of the files to the standard output in the format:

`"%s\n", <file>`

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

If the **–t** option is used with the **–v** option, the standard output format shall be:

```
"%s %u/%u %u %s %d %d:%d %d %s\n", <member mode>, <user ID>,
    <group ID>, <number of bytes in member>,
    <abbreviated month>, <day-of-month>, <hour>,
    <minute>, <year>, <file>
```

where:

<*file*> Shall be the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

<*member* *Shall be formatted the same as the <file mode>* string defined in the STDOUT section of *ls*, except that the first character, the <*entry type*>, is not used; the string represents the file mode of the archive member at the time it was added to or replaced in the archive.

The following represent the last-modification time of a file when it was most recently added to or replaced in the archive:

<*abbreviated month*>
Equivalent to the %*b* format in *date*.

<*day-of-month*>
Equivalent to the %*e* format in *date*.

<*hour*> Equivalent to the %*H* format in *date*.

<*minute*> Equivalent to the %*M* format in *date*.

<*year*> Equivalent to the %*Y* format in *date*.

When *LC_TIME* does not specify the POSIX locale, a different format and order of presentation of these fields relative to each other may be used in a format appropriate in the specified locale.

If the **–x** option is used with the **–v** option, the standard output format shall be:

```
"x – %s\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

STDERR

Used only for diagnostic messages. The diagnostic message about creating a new archive when **–c** is not specified shall not modify the exit status.

OUTPUT FILES

Archives are files with unspecified formats.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The archive format is not described. It is recognized that there are several known *ar* formats, which are not compatible. The *ar* utility is included, however, to allow creation of archives that are intended for use only on one machine. The archive file is specified as a file, and it can be moved as a file. This does allow an archive to be moved from one machine to another machine that uses the same implementation of *ar*.

Utilities such as *pax* (and its forebears *tar* and *cpio*) also provide portable ‘‘archives’’. This is a not a duplication; the *ar* utility is included to provide an interface primarily for *make* and the compilers, based on a historical model.

In historical implementations, the **–q** option (available on XSI-conforming systems) is known to execute quickly because *ar* does not check on whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece-by-piece. These remarks may but need not remain true for a brand new implementation of this utility; hence, these remarks have been moved into the RATIONALE.

BSD implementations historically required applications to provide the **–s** option whenever the archive was supposed to contain a symbol table. As in this volume of IEEE Std. 1003.1-200x, System V historically creates or updates an archive symbol table whenever an object file is removed from, added to, or updated in the archive.

The OPERANDS section requires what might seem to be true without specifying it: the archive cannot truncate the file names below {NAME_MAX}. Some historical implementations do so, however, causing unexpected results for the application. Therefore, this volume of

IEEE Std. 1003.1-200x makes the requirement explicit to avoid misunderstandings.

According to the System V documentation, the options **–dmpqrtx** are not required to begin with a hyphen (''–''). This volume of IEEE Std. 1003.1-200x requires that a conforming application use the leading hyphen.

The archive format used by the 4.4 BSD implementation is documented in this RATIONALE as an example:

> A file created by *ar* begins with the ''magic'' string "!<arch>\n". The rest of the archive is made up of objects, each of which is composed of a header for a file, a possible file name, and the file contents. The header is portable between machine architectures, and, if the file contents are printable, the archive is itself printable.
>
> The header is made up of six ASCII fields, followed by a two-character trailer. The fields are the object name (16 characters), the file last modification time (12 characters), the user and group IDs (each 6 characters), the file mode (8 characters), and the file size (10 characters). All numeric fields are in decimal, except for the file mode, which is in octal.
>
> The modification time is the file *st_mtime* field. The user and group IDs are the file *st_uid* and *st_gid* fields. The file mode is the file *st_mode* field. The file size is the file *st_size* field. The two-byte trailer is the string "<newline>".
>
> Only the name field has any provision for overflow. If any file name is more than 16 characters in length or contains an embedded space, the string "#1/" followed by the ASCII length of the name is written in the name field. The file size (stored in the archive header) is incremented by the length of the name. The name is then written immediately following the archive header.
>
> Any unused characters in any of these fields are written as <space> characters. If any fields are their particular maximum number of characters in length, there is no separation between the fields.
>
> Objects in the archive are always an even number of bytes long; files that are an odd number of bytes long are padded with a <newline> character, although the size in the header does not reflect this.

The *ar* utility description requires that (when all its members are valid object files) *ar* produce an object code library, which the linkage editor can use to extract object modules. If the linkage editor needs a symbol table to permit random access to the archive, *ar* must provide it; however, *ar* does not require a symbol table.

The BSD **–o** option was omitted. It is a rare portable application that uses *ar* to extract object code from a library with concern for its modification time, since this can only be of importance to *make*. Hence, since this functionality is not deemed important for applications portability, the modification time of the extracted files is set to the current time.

There is at least one known implementation (for a small computer) that can accommodate only object files for that system, disallowing mixed object and other files. The ability to handle any type of file is not only historical practice for most implementations, but is also a reasonable expectation.

Consideration was given to changing the output format of *ar* **–tv** to the same format as the output of *ls* **–l**. This would have made parsing the output of *ar* the same as that of *ls*. This was rejected in part because the current *ar* format is commonly used and changes would break historical usage. Second, *ar* gives the user ID and group ID in numeric format separated by a slash. Changing this to be the user name and group name would not be correct if the archive were moved to a machine that contained a different user database. Since *ar* cannot know

whether the archive file was generated on the same machine, it cannot tell what to report.

The text on the **–ur** option combination is historical practice—since one file name can easily represent two different files (for example, **/a/foo** and **/b/foo**), it is reasonable to replace the member in the archive even when the modification time in the archive is identical to that in the file system.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

The **–C** and **–T** options are added.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the Software Development Utilities option.

The STDOUT description is changed for the **–v** option to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

asa — interpret carriage-control characters

SYNOPSIS

FR
```
asa [ file ... ]
```

DESCRIPTION

The *asa* utility shall write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences in an implementation-defined manner.

The first character of every line shall be removed from the input, and the following actions are performed:

If the character removed is:

<space> The rest of the line is output without change.

0 A <newline> character is output, then the rest of the input line.

1 One or more implementation-defined characters that causes an advance to the next page shall be output, followed by the rest of the input line.

+ The <newline> character of the previous line shall be replaced with one or more implementation-defined characters that causes printing to return to column position 1, followed by the rest of the input line. If the '+' is the first character in the input, it shall have the same effect as the <space> character.

The action of the *asa* utility is unspecified upon encountering any character other than those listed above as the first character in a line.

OPTIONS

None.

OPERANDS

file A path name of a text file used for input. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input is used only if no *file* operands are specified; see the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *asa*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The standard output shall be the text from the input file modified as described in the DESCRIPTION section.

STDERR
None.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
None.

EXAMPLES

1. The following command:

   ```
   asa file
   ```

   permits the viewing of *file* (created by a program using FORTRAN-style carriage control characters) on a terminal.

2. The following command:

   ```
   a.out | asa | lp
   ```

   formats the FORTRAN output of **a.out** and directs it to the printer.

RATIONALE
The *asa* utility is needed to map ‘‘standard’’ FORTRAN 77 output into a form acceptable to contemporary printers. Usually, *asa* is used to pipe data to the *lp* utility; see *lp*.

This utility is generally used only by FORTRAN programs. The standard developers decided to retain *asa* to avoid breaking the historical large base of FORTRAN applications that put carriage-control characters in their output files. There is no requirement that a system have a FORTRAN compiler in order to run applications that need *asa*.

Historical implementations have used an ASCII <form-feed> character in response to a 1 and an ASCII <carriage-return> in response to a `'+'`. It is suggested that implementations treat characters other than 0, 1, and `'+'` as <space> in the absence of any compelling reason to do otherwise. However, the action is listed here as ‘‘unspecified’’, permitting an implementation to

provide extensions to access fast multiple-line slewing and channel seeking in a non-portable manner.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the FORTRAN Runtime Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

at — execute commands at a later time

SYNOPSIS

UP

```
at [–m][–f file][–q queuename] –t time_arg
at [–m][–f file][–q queuename] timespec ...
at –r at_job_id ...
at –l –q queuename
at –l [at_job_id ...]
```

DESCRIPTION

The *at* utility shall read commands from standard input and group them together as an *at-job*, to be executed at a later time.

The at-job shall be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask, and other implementation-defined execution-time attributes in effect when the *at* utility is executed shall be retained and used when the at-job is executed.

When the at-job is submitted, the *at_job_id* and scheduled time shall be written to standard error. The *at_job_id* is an identifier that shall be a string consisting solely of alphanumeric characters and the period character. The *at_job_id* shall be assigned by the system when the job is scheduled such that it uniquely identifies a particular job.

User notification and the processing of the job's standard output and standard error are described under the **–m** option.

XSI

Users are permitted to use *at* if their name appears in the file **/usr/lib/cron/at.allow**. If that file does not exist, the file **/usr/lib/cron/at.deny** is checked to determine whether the user should be denied access to *at*. If neither file exists, only a process with the appropriate privileges is allowed to submit a job. If only **at.deny** exists and is empty, global usage is permitted. The **at.allow** and **at.deny** files consist of one user name per line.

OPTIONS

The *at* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f *file* Specify the path name of a file to be used as the source of the at-job, instead of standard input.

–l (The letter ell.) Report all jobs scheduled for the invoking user if no *at_job_id* operands are specified. If *at_job_id*s are specified, report only information for these jobs. The output shall be written to standard output.

–m Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job shall be mailed to the user as well, unless redirected elsewhere. Mail shall be sent even if the job produces no output.

If **–m** is not used, the job's standard output and standard error shall be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the implementation need not notify the user of the job's completion.

5387 **–q** *queuename*

5388 Specify in which queue to schedule a job for submission. When used with the **–l**
5389 option, limit the search to that particular queue. By default, at-jobs shall be
5390 scheduled in queue *a*. In contrast, queue *b* shall be reserved for batch jobs; see
5391 *batch*. The meanings of all other *queuename*s are implementation-defined. If **–q** is |
5392 specified along with either of the **–t** *time_arg* or *timespec* arguments, the results are
5393 unspecified.

5394 **–r** Remove the jobs with the specified *at_job_id* operands that were previously
5395 scheduled by the *at* utility.

5396 **–t** *time_arg* Submit the job to be run at the time specified by the *time* option-argument, which
5397 the application shall ensure has the format as specified by the *touch* **–t** *time* utility.

5398 **OPERANDS**

5399 The following operands shall be supported:

5400 *at_job_id* The name reported by a previous invocation of the *at* utility at the time the job was
5401 scheduled.

5402 *timespec* Submit the job to be run at the date and time specified. All of the *timespec* operands
5403 are interpreted as if they were separated by <space> characters and concatenated,
5404 and shall be parsed as described in the grammar at the end of this section. The date
5405 and time shall be interpreted as being in the timezone of the user (as determined
5406 by the *TZ* variable), unless a timezone name appears as part of *time*, below.

5407 In the POSIX locale, the following describes the three parts of the time
5408 specification string. All of the values from the *LC_TIME* categories in the POSIX
5409 locale shall be recognized in a case-insensitive manner.

5410 *time* The time can be specified as one, two, or four digits. One-digit and
5411 two-digit numbers shall be taken to be hours; four-digit numbers to
5412 be hours and minutes. The time can alternatively be specified as two
5413 numbers separated by a colon, meaning *hour*:*minute*. An AM/PM
5414 indication (one of the values from the **am_pm** keywords in the
5415 *LC_TIME* locale category) can follow the time; otherwise, a 24-hour
5416 clock time shall be understood. A timezone name can also follow to
5417 further qualify the time. The acceptable timezone names are |
5418 implementation-defined, except that they shall be case-insensitive |
5419 and the string **utc** is supported to indicate the time is in Coordinated
5420 Universal Time. In the POSIX locale, the *time* field can also be one of
5421 the following tokens:

5422 **midnight** Indicates the time 12:00 am (00:00).

5423 **noon** Indicates the time 12:00 pm.

5424 **now** Indicates the current day and time. Invoking *at* <**now**>
5425 shall submit an at-job for potentially immediate
5426 execution (that is, subject only to unspecified
5427 scheduling delays).

5428 *date* An optional *date* can be specified as either a month name (one of the
5429 values from the **mon** or **abmon** keywords in the *LC_TIME* locale
5430 category) followed by a day number (and possibly year number
5431 preceded by a comma), or a day of the week (one of the values from
5432 the **day** or **abday** keywords in the *LC_TIME* locale category). In the
5433 POSIX locale, two special days shall be recognized:

today Indicates the current day.

tomorrow Indicates the day following the current day.

If no *date* is given, **today** shall be assumed if the given time is greater than the current time, and **tomorrow** shall be assumed if it is less. If the given month is less than the current month (and no year is given), next year shall be assumed.

increment The optional *increment* shall be a number preceded by a plus sign ('+') and suffixed by one of the following: **minutes**, **hours**, **days**, **weeks**, **months**, or **years**. (The singular forms shall be also accepted.) The keyword **next** shall be equivalent to an increment number of +1. For example, the following are equivalent commands:

```
at 2pm + 1 week
at 2pm next week
```

The following grammar describes the precise format of *timespec* in the POSIX locale. The general conventions for this style of grammar are described in Section 1.10 (on page 2223). This formal syntax shall take precedence over the preceding text syntax description. The longest possible token or delimiter shall be recognized at a given point. When used in a *timespec*, white space shall also delimit tokens.

```
%token hr24clock_hr_min
%token hr24clock_hour
/*
  A hr24clock_hr_min is a one, two, or four-digit number. A one-digit
  or two-digit number constitutes a hr24clock_hour. A hr24clock_hour
  may be any of the single digits 0-9, or may be double digits, ranging
  from 00-23. If a hr24clock_hr_min is a four digit number, the
  first two digits shall be a valid hr24clock_hour, while the last two
  represent the number of minutes, from 00-59.

        inc_period  : "minute" | "minutes"
                    | "hour" | "hours"
                    | "day" | "days"
                    | "week" | "weeks"
                    | "month" | "months"
                    | "year" | "years"
                    ;
```

STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 2235). The standard input shall only be used if no **–f** *file* option is specified.

INPUT FILES

See the STDIN section.

XSI The text files **/usr/lib/cron/at.allow** and **/usr/lib/cron/at.deny** contain user names, one per line, of users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *at*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LC_TIME Determine the format and contents for date and time strings written and accepted by *at*.

SHELL Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; or any of the preceding accompanied by a warning diagnostic about which was chosen.

TZ Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it shall override *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

In the POSIX locale, the following shall be written to the standard output for each job when jobs are listed in response to the **–l** option:

```
"%s\t%s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

STDERR

In the POSIX locale, the following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* has the same format as is described in the STDOUT section. Neither this, nor warning messages concerning the selection of the command interpreter, shall be considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The *at* utility successfully submitted, removed, or listed a job or jobs.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled, removed, or listed.

APPLICATION USAGE

The format of the *at* command line shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps, and priority inherited from the invoking environment are lost.

Some implementations do not allow substitution of different shells using *SHELL*. System V systems, for example, have used the login shell value for the user in **/etc/passwd**. To select reliably another command interpreter, the user must include it as part of the script, such as:

```
$ at 1800
myshell myscript
job ... at ...
$
```

EXAMPLES

1. This sequence can be used at a terminal:

   ```
   at –m 0730 tomorrow
   sort < file >outfile
   EOT
   ```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

   ```
   at now + 1 hour <<!
   diff file1 file2 2>&1 >outfile | mailx mygroup
   !
   ```

3. To have a job reschedule itself, *at* can be invoked from within the at-job. For example, this daily processing script named **my.daily** runs every day (although *crontab* is a more appropriate vehicle for such work):

   ```
   # my.daily runs every day
   daily processing
   at now tomorrow < my.daily
   ```

4. The spacing of the three portions of the POSIX locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentation include:

   ```
   at 0815am Jan 24
   at 8 :15amjan24
   at now "+ 1day"
   at 5 pm FRIday
   at ’17
       utc+
       30minutes’
   ```

RATIONALE

The *at* utility reads from standard input the commands to be executed at a later time. It may be useful to redirect standard output and standard error within the specified commands.

The **–t** *time* option was added as a new capability to support an internationalized way of specifying a time for execution of the submitted job.

Early proposals added a ''jobname'' concept as a way of giving submitted jobs names that are meaningful to the user submitting them. The historical, system-specified *at_job_id* gives no indication of what the job is. Upon further reflection, it was decided that the benefit of this was not worth the change in historical interface. It is anticipated that considerably more sophisticated ways of controlling background or batch work will be the subject of a future version of this volume of IEEE Std. 1003.1-200x.

The **–q** option historically has been an undocumented option, used mainly by the *batch* utility.

The System V **–m** option was added to provide a method for informing users that an at-job had completed. Otherwise, users are only informed when output to standard error or standard output are not redirected.

The behavior of *at* <*now*> was changed in an early proposal from being unspecified to submitting a job for potentially immediate execution. Historical BSD *at* implementations support this. Historical System V implementations give an error in that case, but a change to the System V versions should have no backwards compatibility ramifications.

On BSD-based systems, a **–u** *user* option has allowed those with appropriate privileges to access the work of other users. Since this is primarily a system administration feature and is not universally implemented, it has been omitted. Similarly, a specification for the output format for user with appropriate privileges viewing the queues of other users has been omitted.

The **–f** *file* option from System V is used instead of the BSD method of using the last operand as the path name. The BSD method is ambiguous—does:

```
at 1200 friday
```

mean the same thing if there is a file named **friday** in the current directory?

The *at_job_id* is composed of a limited character set in historical practice, and it is mandated here to invalidate systems that might try using characters that require shell quoting or that could not be easily parsed by shell scripts.

The *at* utility varies between System V and BSD systems in the way timezones are used. On System V systems, the *TZ* variable affects the at-job submission times and the times displayed for the user. On BSD systems, *TZ* is not taken into account. The BSD behavior is easily achieved with the current specification. If the user wishes to have the timezone default to that of the system, they merely need to issue the *at* command immediately following an unsetting or null assignment to *TZ*. For example:

```
TZ= at noon ...
```

gives the desired BSD result.

While the *yacc*-like grammar specified in the OPERANDS section is lexically unambiguous with respect to the digit strings, a lexical analyzer would probably be written to look for and return digit strings in those cases. The parser could then check whether the digit string returned is a valid *day_number*, *year_number*, and so on, based on the context.

FUTURE DIRECTIONS

None.

batch, *crontab*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO/IEC 9945-2:1993 standard.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- If **–m** is not used, the job's standard output and standard error are provided to the user by mail.

The effects of using the **–q** and **–t** options as defined in the IEEE P1003.2b draft standard are specified.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

NAME

awk — pattern scanning and processing language

SYNOPSIS

```
awk [–F ERE][–v assignment] ... program [argument ...]
awk [–F ERE] –f progfile ... [–v assignment] ...[argument ...]
```

DESCRIPTION

The *awk* utility shall execute programs written in the *awk* programming language, which is specialized for textual data manipulation. An *awk* program is a sequence of patterns and corresponding actions. When input is read that matches a pattern, the action associated with that pattern is carried out.

Input shall be interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the **RS** built-in variable. Each record of input shall be matched in turn against each pattern in the program. For each pattern matched, the associated action shall be executed.

The *awk* utility shall interpret each input record as a sequence of fields where, by default, a field is a string of non-<blank> characters. This default white-space field delimiter can be changed by using the **FS** built-in variable or the **–F** *ERE*. The *awk* utility shall denote the first field in a record $1, the second $2, and so on. The symbol $0 shall refer to the entire record; setting any other field causes the re-evaluation of $0. Assigning to $0 shall reset the values of all other fields and the **NF** built-in variable.

OPTIONS

The *awk* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–F *ERE* Define the input field separator to be the extended regular expression *ERE*, before any input is read; see **Regular Expressions** (on page 2375).

–f *progfile* Specify the path name of the file *progfile* containing an *awk* program. If multiple instances of this option are specified, the concatenation of the files specified as *progfile* in the order specified shall be the *awk* program. The *awk* program can alternatively be specified in the command line as a single argument.

–v *assignment*
The application shall ensure that the *assignment* argument is in the same form as an *assignment* operand. The specified variable assignment shall occur prior to executing the *awk* program, including the actions associated with **BEGIN** patterns (if any). Multiple occurrences of this option can be specified.

OPERANDS

The following operands shall be supported:

program If no **–f** option is specified, the first operand to *awk* shall be the text of the *awk* program. The application shall supply the *program* operand as a single argument to *awk*. If the text does not end in a <newline> character, *awk* shall interpret the text as if it did.

argument Either of the following two types of *argument* can be intermixed:

file A path name of a file that contains the input to be read, which is matched against the set of patterns in the program. If no *file* operands are specified, or if a *file* operand is `'–'`, the standard input shall be used.

assignment An operand that begins with an underscore or alphabetic character from the portable character set (see the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set), followed by a sequence of underscores, digits, and alphabetics from the portable character set, followed by the '=' character, shall specify a variable assignment rather than a path name. The characters before the '=' represent the name of an *awk* variable; if that name is an *awk* reserved word (see **Grammar** (on page 2384)) the behavior is undefined. The characters following the equal sign shall be interpreted as if they appeared in the *awk* program preceded and followed by a double-quote ('"') character, as a **STRING** token (see **Grammar** (on page 2384)), except that if the last character is an unescaped backslash, it shall be interpreted as a literal backslash rather than as the first character of the sequence "\"". The variable shall be assigned the value of that **STRING** token and, if appropriate, shall be considered a *numeric string* (see **Expressions in awk** (on page 2370)), the variable shall also be assigned its numeric value. Each such variable assignment shall occur just prior to the processing of the following *file*, if any. Thus, an assignment before the first *file* argument shall be executed after the **BEGIN** actions (if any), while an assignment after the last *file* argument shall occur before the **END** actions (if any). If there are no *file* arguments, assignments shall be executed before processing the standard input.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '–'; see the INPUT FILES section. If the *awk* program contains no actions and no patterns, but is otherwise a valid *awk* program, standard input and any *file* operands shall not be read and *awk* shall exit with a return status of zero.

INPUT FILES

Input files to the *awk* program from any of the following sources shall be text files:

- Any *file* operands or their equivalents, achieved by modifying the *awk* variables **ARGV** and **ARGC**
- Standard input in the absence of any *file* operands
- Arguments to the **getline** function

Whether the variable **RS** is set to a value other than a <newline> character or not, for these files, implementations shall support records terminated with the specified separator up to {LINE_MAX} bytes and may support longer records.

If **–f** *progfile* is specified, the application shall ensure that the files named by each of the *progfile* option-arguments are text files containing an *awk* program.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *awk*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions and in comparisons of string values.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the identification of characters as letters, and the mapping of uppercase and lowercase characters for the **toupper** and **tolower** functions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values, and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments).

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path when looking for commands executed by *system*(*expr*), or input and output pipes; see the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

In addition, all environment variables shall be visible via the *awk* variable **ENVIRON**.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The nature of the output files depends on the *awk* program.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

The nature of the output files depends on the *awk* program.

EXTENDED DESCRIPTION

Overall Program Structure

An *awk* program is composed of pairs of the form:

```
pattern { action }
```

Either the pattern or the action (including the enclosing brace characters) can be omitted.

A missing pattern shall match any record of input, and a missing action shall be equivalent to:

```
{ print }
```

Execution of the *awk* program shall start by first executing the actions associated with all **BEGIN** patterns in the order they occur in the program. Then each *file* operand (or standard input if no

files were specified) shall be processed in turn by reading data from the file until a record separator is seen (<newline> by default). Before the first reference to a field in the record is evaluated, the record shall be split into fields, according to the rules in **Regular Expressions** (on page 2375), using the value of **FS** that was current at the time the record was read. Each pattern in the program then shall be evaluated in the order of occurrence, and the action associated with each pattern that matches the current record executed. The action for a matching pattern shall be executed before evaluating subsequent patterns. Finally, the actions associated with all **END** patterns shall be executed in the order they occur in the program.

Expressions in awk

Expressions describe computations used in *patterns* and *actions*. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators shall be evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent any expression, while *lvalue* represents any entity that can be assigned to (that is, on the left side of an assignment operator). The precise syntax of expressions is given in **Grammar** (on page 2384).

Table 4-1 Expressions in Decreasing Precedence in *awk*

Syntax	Name	Type of Result	Associativity
(*expr*)	Grouping	Type of *expr*	N/A
$*expr*	Field reference	String	N/A
++ *lvalue*	Pre-increment	Numeric	N/A
–– *lvalue*	Pre-decrement	Numeric	N/A
lvalue ++	Post-increment	Numeric	N/A
lvalue ––	Post-decrement	Numeric	N/A
expr ^ *expr*	Exponentiation	Numeric	Right
! *expr*	Logical not	Numeric	N/A
+ *expr*	Unary plus	Numeric	N/A
– *expr*	Unary minus	Numeric	N/A
expr * *expr*	Multiplication	Numeric	Left
expr / *expr*	Division	Numeric	Left
expr % *expr*	Modulus	Numeric	Left
expr + *expr*	Addition	Numeric	Left
expr – *expr*	Subtraction	Numeric	Left
expr *expr*	String concatenation	String	Left
expr < *expr*	Less than	Numeric	None
expr <= *expr*	Less than or equal to	Numeric	None
expr != *expr*	Not equal to	Numeric	None
expr == *expr*	Equal to	Numeric	None
expr > *expr*	Greater than	Numeric	None
expr >= *expr*	Greater than or equal to	Numeric	None
expr ~ *expr*	ERE match	Numeric	None
expr !~ *expr*	ERE non-match	Numeric	None

Syntax	Name	Type of Result	Associativity
expr in array	Array membership	Numeric	Left
(*index*) in *array*	Multi-dimension array membership	Numeric	Left
expr && *expr*	Logical AND	Numeric	Left
expr || *expr*	Logical OR	Numeric	Left
expr1 ? *expr2* : *expr3*	Conditional expression	Type of selected *expr2* or *expr3*	Right
lvalue ^= *expr*	Exponentiation assignment	Numeric	Right
lvalue %= *expr*	Modulus assignment	Numeric	Right
lvalue *= *expr*	Multiplication assignment	Numeric	Right
lvalue /= *expr*	Division assignment	Numeric	Right
lvalue += *expr*	Addition assignment	Numeric	Right
lvalue –= *expr*	Subtraction assignment	Numeric	Right
lvalue = *expr*	Assignment	Type of *expr*	Right

Each expression shall have either a string value, a numeric value, or both. Except as stated for specific contexts, the value of an expression shall be implicitly converted to the type needed for the context in which it is used. A string value shall be converted to a numeric value by the equivalent of the following calls to functions defined by the ISO C standard:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer shall be converted to a string by the equivalent of a call to the **sprintf** function (see **String Functions** (on page 2381)) with the string "%d" as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value shall be converted to a string by the equivalent of a call to the **sprintf** function with the value of the variable **CONVFMT** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. The result of the conversion is unspecified if the value of **CONVFMT** is not a floating-point format specification. This volume of IEEE Std. 1003.1-200x specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to it, or can force it to be treated as a string by concatenating the null string (" ") to it.

A string value shall be considered a *numeric string* if it comes from one of the following:

1. Field variables
2. Input from the *getline*( ) function
3. **FILENAME**
4. **ARGV** array elements
5. **ENVIRON** array elements
6. Array elements created by the *split*( ) function
7. A command line variable assignment
8. Variable assignment from another numeric string variable

and after all the following conversions have been applied, the resulting string would lexically be recognized as a **NUMBER** token as described by the lexical conventions in **Grammar** (on page 2384):

- All leading and trailing <blank>s are discarded
- If the first non-<blank> character is `'+'` or `'-'`, it is discarded
- Changing each occurrence of the decimal point character from the current locale to a period

If a `'–'` character is ignored in the preceding description, the numeric value of the *numeric string* shall be the negation of the numeric value of the recognized **NUMBER** token. Otherwise, the numeric value of the *numeric string* shall be the numeric value of the recognized **NUMBER** token. Whether or not a string is a *numeric string* shall be relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero shall be treated as false and any other value shall be treated as true. Otherwise, a string value of the null string shall be treated as false and any other value shall be treated as true. A Boolean context shall be one of the following:

- The first subexpression of a conditional expression
- An expression operated on by logical NOT, logical AND, or logical OR
- The second expression of a **for** statement
- The expression of an **if** statement
- The expression of the **while** clause in either a **while** or **do**...**while** statement
- An expression used as a pattern (as in Overall Program Structure)

All arithmetic shall follow the semantics of floating-point arithmetic as specified by the ISO C standard.

The value of the expression:

expr1 `^` *expr2*

shall be equivalent to the value returned by the ISO C standard function call:

`pow(`*expr1*`, `*expr2*`)`

The expression:

lvalue `^=` *expr*

shall be equivalent to the ISO C standard expression:

lvalue `= pow(`*lvalue*`, `*expr*`)`

except that *lvalue* shall be evaluated only once. The value of the expression:

expr1 `%` *expr2*

shall be equivalent to the value returned by the ISO C standard function call:

`fmod(`*expr1*`, `*expr2*`)`

The expression:

lvalue `%=` *expr*

shall be equivalent to the ISO C standard expression:

lvalue `= fmod(`*lvalue*`, `*expr*`)`

except that *lvalue* shall be evaluated only once.

Variables and fields shall be set by the assignment statement:

lvalue = *expression*

and the type of *expression* shall determine the resulting variable type. The assignment includes the arithmetic assignments ("+=", "−=", "*=", "/=", "%=", "^=", "++", "−−") all of which shall produce a numeric result. The left-hand side of an assignment and the target of increment and decrement operators can be one of a variable, an array with index, or a field selector.

The *awk* language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They shall initially be empty, and their sizes shall change dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and thus as an expression, as described in the grammar; see **Grammar** (on page 2384). Unsubscripted array names can be used in only the following contexts:

- A parameter in a function definition or function call
- The **NAME** token following any use of the keyword **in** as specified in the grammar (see **Grammar** (on page 2384)); if the name used in this context is not an array name, the behavior is undefined

A valid array *index* shall consist of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because *awk* arrays are really one-dimensional, such a comma-separated list shall be converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the **SUBSEP** variable. Thus, the following two index operations shall be equivalent:

var[*expr1*, *expr2*, ... *exprn*]

var[*expr1* SUBSEP *expr2* SUBSEP ... SUBSEP *exprn*]

The application shall ensure that a multi-dimensioned *index* used with the **in** operator is parenthesized. The **in** operator, which tests for the existence of a particular array element, shall not cause that element to exist. Any other reference to a nonexistent array element shall automatically create it.

Comparisons (with the '<', "<=", "!=", "==", '>', and ">=" operators) shall be made numerically if both operands are numeric, if one is numeric and the other has a string value that is a numeric string, or if one is numeric and the other has the uninitialized value. Otherwise, operands shall be converted to strings as required and a string comparison shall be made using the locale-specific collation sequence. The value of the comparison expression shall be 1 if the relation is true, or 0 if the relation is false.

Variables and Special Variables

Variables can be used in an *awk* program by referencing them. With the exception of function parameters (see **User-Defined Functions** (on page 2383)), they are not explicitly declared. Function parameter names shall be local to the function; all other variable names shall be global. The same name shall not be used as both a function parameter name and as the name of a function or a special *awk* variable. The same name shall not be used both as a variable name with global scope and as the name of a function. The same name shall not be used within the same scope both as a scalar variable and as an array. Uninitialized variables, including scalar variables, array elements, and field variables, shall have an uninitialized value. An uninitialized value shall have both a numeric value of zero and a string value of the empty string. Evaluation of variables with an uninitialized value, to either string or numeric, shall be determined by the context in which they are used.

Field variables shall be designated by a '$' followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables can be created by assigning a value to them. References to nonexistent fields (that is, fields after $**NF**), shall evaluate to the uninitialized value. Such references shall not create new fields. However, assigning to a nonexistent field (for example, $(**NF**+2)=5) shall increase the value of **NF**; create any intervening fields with the uninitialized value; and cause the value of $0 to be recomputed, with the fields being separated by the value of **OFS**. Each field variable shall have a string value or an uninitialized value when created. Field variables shall have the uninitialized value when created from $0 using **FS** and the variable does not contain any characters. If appropriate, the field variable shall be considered a numeric string (see **Expressions in awk** (on page 2370)).

Implementations shall support the following other special variables that are set by *awk*:

ARGC The number of elements in the **ARGV** array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to **ARGC**–1.

The arguments in **ARGV** can be modified or added to; **ARGC** can be altered. As each input file ends, *awk* shall treat the next non-null element of **ARGV**, up to the current value of **ARGC**–1, inclusive, as the name of the next input file. Thus, setting an element of **ARGV** to null means that it shall not be treated as an input file. The name '–' indicates the standard input. If an argument matches the format of an *assignment* operand, this argument shall be treated as an assignment rather than a *file* argument.

CONVFMT The **printf** format for converting numbers to strings (except for output statements, where **OFMT** is used); "%.6g" by default.

ENVIRON The variable **ENVIRON** is an array representing the value of the environment, as described in the *exec* functions defined in the System Interfaces volume of IEEE Std. 1003.1-200x. The indices of the array shall be strings consisting of the names of the environment variables, and the value of each array element is a string consisting of the value of that variable. If appropriate, the environment variable shall be considered a *numeric string* (see **Expressions in awk** (on page 2370)), the array element shall also have its numeric value.

In all cases where the behavior of *awk* is affected by environment variables (including the environment of any commands that *awk* executes via the **system** function or via pipeline redirections with the **print** statement, the **printf** statement, or the **getline** function), the environment used shall be the environment at the time *awk* began executing; it is implementation-defined whether any modification of **ENVIRON** affects this environment.

FILENAME A path name of the current input file. Inside a **BEGIN** action the value is undefined. Inside an **END** action the value is the name of the last input file processed.

FNR The ordinal number of the current record in the current file. Inside a **BEGIN** action the value is zero. Inside an **END** action the value is the number of the last record processed in the last file processed.

FS Input field separator regular expression; a <space> character by default.

NF The number of fields in the current record. Inside a **BEGIN** action, the use of **NF** is undefined unless a **getline** function without a *var* argument is executed

previously. Inside an **END** action, **NF** retains the value it had for the last record read, unless a subsequent redirected, **getline** function without a *var* argument is performed prior to entering the **END** action.

NR The ordinal number of the current record from the start of input. Inside a **BEGIN** action the value is zero. Inside an **END** action the value is the number of the last record processed.

OFMT The **printf** format for converting numbers to strings in output statements (see **Output Statements** (on page 2379)); `"%.6g"` by default. The result of the conversion is unspecified if the value of **OFMT** is not a floating-point format specification.

OFS The **print** statement output field separation; <space> by default.

ORS The **print** statement output record separator; a <newline> character by default.

RLENGTH The length of the string matched by the **match** function.

RS The first character of the string value of **RS** is the input record separator; a <newline> character by default. If **RS** contains more than one character, the results are unspecified. If **RS** is null, then records are separated by sequences of one or more blank lines, leading or trailing blank lines do not result in empty records at the beginning or end of the input, and a <newline> character is always a field separator, no matter what the value of **FS** is.

RSTART The starting position of the string matched by the **match** function, numbering from 1. This is always equivalent to the return value of the **match** function.

SUBSEP The subscript separator string for multi-dimensional arrays; the default value is implementation-defined.

Regular Expressions

The *awk* utility shall make use of the extended regular expression notation (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.4, Extended Regular Expressions) except that it shall allow the use of C-language conventions for escaping special characters within the EREs, as specified in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) and the following table; these escape sequences shall be recognized both inside and outside bracket expressions. Note that records need not be separated by <newline> characters and string constants can contain <newline> characters, so even the `"\n"` sequence is valid in *awk* EREs. Using a slash character within an ERE requires the escaping shown in the following table.

Table 4-2 Escape Sequences in *awk*

Escape Sequence	Description	Meaning
\"	Backslash quotation-mark	Quotation-mark character
\/	Backslash slash	Slash character
\ddd	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading '\' for each byte.
\c	A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation ('\\', '\a', '\b', '\f', '\n', '\r', '\t', '\v')	Undefined

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, '~' and "!~". These operators shall interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the '~' expression shall evaluate to a value of 1, and the "!~" expression shall evaluate to a value of 0. (The regular expression matching operation is as defined by the term matched in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.1, Regular Expression Definitions, where a match occurs on any part of the string unless the regular expression is limited with the circumflex or dollar sign special characters.) If the regular expression does not match the string, the '~' expression shall evaluate to a value of 0, and the "!~" expression shall evaluate to a value of 1. If the right-hand operand is any expression other than the lexical token **ERE**, the string value of the expression shall be interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions shall also be applied in determining the value of a string literal (the lexical token **STRING**), and thus shall be applied a second time when a string literal is used in this context.

When an **ERE** token appears as an expression in any context other than as the right-hand of the '~' or "!~" operator or as one of the built-in function arguments described below, the value of the resulting expression shall be the equivalent of:

```
$0 ~ /ere/
```

The *ere* argument to the **gsub**, **match**, **sub** functions, and the *fs* argument to the **split** function (see **String Functions** (on page 2381)) shall be interpreted as extended regular expressions. These can be either **ERE** tokens or arbitrary expressions, and shall be interpreted in the same manner as the right-hand side of the '~' or "!~" operator.

An extended regular expression can be used to separate fields by using the –**F** *ERE* option or by assigning a string containing the expression to the built-in variable **FS**. The default value of the **FS** variable shall be a single <space> character. The following describes **FS** behavior:

1. If **FS** is a null string, the behavior is unspecified.
2. If **FS** is a single character:
   a. If **FS** is the <space> character, skip leading and trailing <blank> characters; fields shall be delimited by sets of one or more <blank> characters.
   b. Otherwise, if **FS** is any other character *c*, fields shall be delimited by each single occurrence of *c*.
3. Otherwise, the string value of **FS** shall be considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression shall delimit fields.

Except for the '~' and "!~" operators, and in the **gsub**, **match**, **split**, and **sub** built-in functions, ERE matching shall be based on input records; that is, record separator characters (the first character of the value of the variable **RS**, <newline> by default) cannot be embedded in the expression, and no expression shall match the record separator character. If the record separator is not <newline>, <newline> characters embedded in the expression can be matched. For the '~' and "!~" operators, and in those four built-in functions, ERE matching shall be based on text strings; that is, any character (including <newline> and the record separator) can be embedded in the pattern, and an appropriate pattern shall match any character. However, in all *awk* ERE matching, the use of one or more NUL characters in the pattern, input record, or text string produces undefined results.

Patterns

A *pattern* is any valid *expression*, a range specified by two expressions separated by comma, or one of the two special patterns **BEGIN** or **END**.

Special Patterns

The *awk* utility shall recognize two special patterns, **BEGIN** and **END**. Each **BEGIN** pattern shall be matched once and its associated action executed before the first record of input is read (except possibly by use of the **getline** function—see **Input/Output and General Functions** (on page 2382)—in a prior **BEGIN** action) and before command line assignment is done. Each **END** pattern shall be matched once and its associated action executed after the last record of input has been read. These two patterns shall have associated actions.

BEGIN and **END** shall not combine with other patterns. Multiple **BEGIN** and **END** patterns shall be allowed. The actions associated with the **BEGIN** patterns shall be executed in the order specified in the program, as are the **END** actions. An **END** pattern can precede a **BEGIN** pattern in a program.

If an *awk* program consists of only actions with the pattern **BEGIN**, and the **BEGIN** action contains no **getline** function, *awk* shall exit without reading its input when the last statement in the last **BEGIN** action is executed. If an *awk* program consists of only actions with the pattern **END** or only actions with the patterns **BEGIN** and **END**, the input shall be read before the statements in the **END** actions are executed.

6190 **Expression Patterns**

6191 An expression pattern shall be evaluated as if it were an expression in a Boolean context. If the
6192 result is true, the pattern shall be considered to match, and the associated action (if any) shall be
6193 executed. If the result is false, the action shall not be executed.

6194 **Pattern Ranges**

6195 A pattern range consists of two expressions separated by a comma; in this case, the action shall
6196 be performed for all records between a match of the first expression and the following match of
6197 the second expression, inclusive. At this point, the pattern range can be repeated starting at
6198 input records subsequent to the end of the matched range.

6199 **Actions**

6200 An action is a sequence of statements as shown in the grammar in **Grammar** (on page 2384).
6201 Any single statement can be replaced by a statement list enclosed in braces. The application shall
6202 ensure that statements in a statement list are separated by <newline> characters or semicolons,
6203 and are executed sequentially in the order that they appear.

6204 The *expression* acting as the conditional in an **if** statement shall be evaluated and if it is non-zero
6205 or non-null, the following *statement* shall be executed; otherwise, if **else** is present, the statement
6206 following the **else** shall be executed.

6207 The **if**, **while**, **do**...**while**, **for**, **break**, and **continue** statements are based on the ISO C standard,
6208 except that the Boolean expressions shall be treated as described in **Expressions in awk** (on page
6209 2370), and except in the case of:

6210 `for (`*`variable`* `in` *`array`*`)`

6211 which shall iterate, assigning each *index* of *array* to *variable* in an unspecified order. The results of
6212 adding new elements to *array* within such a **for** loop are undefined. If a **break** or **continue**
6213 statement occurs outside of a loop, the behavior is undefined.

6214 The **delete** statement shall remove an individual array element. Thus, the following code deletes
6215 an entire array:

6216 ```
6217 for (index in array)
        delete array[index]
```

6218 The **next** statement shall cause all further processing of the current input record to be
6219 abandoned. The behavior is undefined if a **next** statement appears or is invoked in a **BEGIN** or
6220 **END** action.

6221 The **exit** statement shall invoke all **END** actions in the order in which they occur in the program
6222 source and then terminate the program without reading further input. An **exit** statement inside
6223 an **END** action shall terminate the program without further execution of **END** actions. If an
6224 expression is specified in an **exit** statement, its numeric value shall be the exit status of *awk*,
6225 unless subsequent errors are encountered or a subsequent **exit** statement with an expression is
6226 executed.
```

Output Statements

Both **print** and **printf** statements shall write to standard output by default. The output shall be written to the location specified by *output_redirection* if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the *expression* shall be evaluated to produce a string that is used as a path name into which to write (for '>' or ">>") or as a command to be executed (for '|'). Using the first two forms, if the file of that name is not currently open, it shall be opened, creating it if necessary and using the first form, truncating the file. The output then shall be appended to the file. As long as the file remains open, subsequent calls in which *expression* evaluates to the same string value shall simply append output to the file. The file remains open until the **close** function (see **Input/Output and General Functions** (on page 2382)) is called with an expression that evaluates to the same string value.

The third form shall write output onto a stream piped to the input of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x with the value of *expression* as the *command* argument and a value of *w* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall write output to the existing stream. The stream shall remain open until the **close** function (see **Input/Output and General Functions** (on page 2382)) is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x.

As described in detail by the grammar in **Grammar** (on page 2384), these output statements shall take a comma-separated list of *expression*s referred to in the grammar by the non-terminal symbols **expr_list**, **print_expr_list**, or **print_expr_list_opt**. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The **print** statement shall write the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable **OFS** above), and terminated by the output record separator (see variable **ORS** above). All expression arguments shall be taken as strings, being converted if necessary; this conversion shall be as described in **Expressions in awk** (on page 2370), with the exception that the **printf** format in **OFMT** shall be used instead of the value in **CONVFMT**. An empty expression list shall stand for the whole input record ($0).

The **printf** statement shall produce output based on a notation similar to the File Format Notation used to describe file formats in this volume of IEEE Std. 1003.1-200x (see the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation). Output shall be produced as specified with the first expression argument as the string *format* and subsequent expression arguments as the strings *arg1* to *argn*, inclusive, with the following exceptions:

1. The *format* shall be an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The <space> character in the *format* string, in any context other than a *flag* of a conversion specification, shall be treated as an ordinary character that is copied to the output.

2. If the character set contains a 'Δ' character and that character appears in the *format* string, it shall be treated as an ordinary character that is copied to the output.

3. The *escape sequences* beginning with a backslash character shall be treated as sequences of ordinary characters that are copied to the output. Note that these same sequences shall be interpreted lexically by *awk* when they appear in literal strings, but they shall not be treated specially by the **printf** statement.
4. A *field width* or *precision* can be specified as the `'*'` character instead of a digit string. In this case the next argument from the expression list shall be fetched and its numeric value taken as the field width or precision.
5. The implementation shall not precede or follow output from the *d* or *u* conversion specifications with <blank> characters not specified by the *format* string.
6. The implementation shall not precede output from the *o* conversion specification with leading zeros not specified by the *format* string.
7. For the *c* conversion specification: if the argument has a numeric value, the character whose encoding is that value shall be output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value shall be output; if the string does not contain any characters, the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument shall be evaluated. With the exception of the *c* conversion, the value shall be converted (according to the rules specified in **Expressions in awk** (on page 2370)) to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.
10. If any character sequence in the *format* string begins with a `'%'` character, but does not form a valid conversion specification, the behavior is unspecified.

Both **print** and **printf** can output at least {LINE_MAX} bytes.

Functions

The *awk* language has a variety of built-in functions: arithmetic, string, input/output, and general.

Arithmetic Functions

The arithmetic functions, except for **int**, shall be based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar (see **Grammar** (on page 2384)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `"[]"` brackets), such use is undefined.

atan2(*y*,*x*) Return arctangent of *y*/*x* in radians in the range –{π} to {.

cos(*x*) Return cosine of *x*, where *x* is in radians.

sin(*x*) Return sine of *x*, where *x* is in radians.

exp(*x*) Return the exponential function of *x*.

log(*x*) Return the natural logarithm of *x*.

sqrt(*x*) Return the square root of *x*.

int(*x*) Truncate its argument to an integer. It shall be truncated toward 0 when *x*>0.

rand( ) Return a random number *n*, such that 0≤*n*<1.

srand([*expr***])** Set the seed value for *rand* to *expr* or use the time of day if *expr* is omitted. The previous seed value shall be returned.

String Functions

The string functions in the following list shall be supported. Although the grammar (see **Grammar** (on page 2384)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the "[]" brackets), such use is undefined.

gsub(*ere*, *repl***[**, *in***]**)
Behave like **sub** (see below), except that it shall replace all occurrences of the regular expression (like the *ed* utility global substitute) in $0 or in the *in* argument, when specified.

index(*s*, *t*) Return the position, in characters, numbering from 1, in string *s* where string *t* first occurs, or zero if it does not occur at all.

length[([*s***])]** Return the length, in characters, of its argument taken as a string, or of the whole record, $0, if there is no argument.

match(*s*, *ere*) Return the position, in characters, numbering from 1, in string *s* where the extended regular expression *ere* occurs, or zero if it does not occur at all. RSTART shall be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH shall be set to the length of the matched string, –1 if no match is found.

split(*s*, *a***[**, *fs* **]**)
Split the string *s* into array elements *a*[1], *a*[2], ..., *a*[*n*], and return *n*. All elements of the array shall be deleted before the split is performed. The separation shall be done with the ERE *fs* or with the field separator **FS** if *fs* is not given. Each array element shall have a string value when created and, if appropriate, the array element shall be considered a numeric string (see **Expressions in awk** (on page 2370)). The effect of a null string as the value of *fs* is unspecified.

sprintf(*fmt*, *expr*, *expr*, ...)
Format the expressions according to the **printf** format given by *fmt* and return the resulting string.

sub(*ere*, *repl***[**, *in* **])**
Substitute the string *repl* in place of the first instance of the extended regular expression *ERE* in string *in* and return the number of substitutions. An ampersand ('&') appearing in the string *repl* shall be replaced by the string from *in* that matches the ERE. An ampersand preceded with a backslash ('\') shall be interpreted as the literal ampersand character. Any other occurrence of a backslash (for example, preceding any other character) shall be treated as a literal backslash character. Note that if *repl* is a string literal (the lexical token **STRING**; see **Grammar** (on page 2384)), the handling of the ampersand character occurs after any lexical processing, including any lexical backslash escape sequence processing. If *in* is specified and it is not an *lvalue* (see **Expressions in awk** (on page 2370)), the behavior is undefined. If *in* is omitted, *awk* shall use the current record ($0) in its place.

substr(*s*, *m*[, *n*])
: Return the at most *n*-character substring of *s* that begins at position *m*, numbering from 1. If *n* is missing, or if *n* specifies more characters than are left in the string, the length of the substring shall be limited by the length of the string *s*.

tolower(*s*)
: Return a string based on the string *s*. Each character in *s* that is an uppercase letter specified to have a **tolower** mapping by the *LC_CTYPE* category of the current locale shall be replaced in the returned string by the lowercase letter specified by the mapping. Other characters in *s* shall be unchanged in the returned string.

toupper(*s*)
: Return a string based on the string *s*. Each character in *s* that is a lowercase letter specified to have a **toupper** mapping by the *LC_CTYPE* category of the current locale is replaced in the returned string by the uppercase letter specified by the mapping. Other characters in *s* are unchanged in the returned string.

All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued expression that is a regular expression as defined in **Regular Expressions** (on page 2375).

Input/Output and General Functions

The input/output and general functions are:

close(*expression*)
: Close the file or pipe opened by a **print** or **printf** statement or a call to **getline** with the same string-valued *expression*. The limit on the number of open *expression* arguments is implementation-defined. If the close was successful, the function shall return zero; otherwise, it shall return non-zero.

expression | **getline [***var***]**
: Read a record of input from a stream piped from the output of a command. The stream shall be created if no stream is currently open with the value of *expression* as its command name. The stream created shall be equivalent to one created by a call to the *popen*( ) function with the value of *expression* as the *command* argument and a value of *r* as the *mode* argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value shall read subsequent records from the stream. The stream shall remain open until the **close** function is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function. If *var* is missing, $0 and **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered a numeric string (see **Expressions in awk** (on page 2370)).

  The **getline** operator can form ambiguous constructs when there are unparenthesized operators (including concatenate) to the left of the `'|'` (to the beginning of the expression containing **getline**). In the context of the `'$'` operator, `'|'` shall behave as if it had a lower precedence than `'$'`. The result of evaluating other operators is unspecified, and portable applications shall parenthesize properly all such usages.

getline
: Set $0 to the next input record from the current input file. This form of **getline** shall set the **NF**, **NR**, and **FNR** variables.

getline *var*
: Set variable *var* to the next input record from the current input file and, if appropriate, *var* shall be considered a numeric string (see **Expressions in awk** (on page 2370)). This form of **getline** shall set the **FNR** and **NR** variables.

getline [*var***]** < *expression*
: Read the next record of input from a named file. The *expression* shall be evaluated

6405 to produce a string that is used as a path name. If the file of that name is not
6406 currently open, it shall be opened. As long as the stream remains open, subsequent
6407 calls in which *expression* evaluates to the same string value shall read subsequent
6408 records from the file. The file shall remain open until the **close** function is called
6409 with an expression that evaluates to the same string value. If *var* is missing, $0 and
6410 **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered
6411 a numeric string (see **Expressions in awk** (on page 2370)).

6412 The **getline** operator can form ambiguous constructs when there are
6413 unparenthesized binary operators (including concatenate) to the right of the `'<'`
6414 (up to the end of the expression containing the **getline**). The result of evaluating
6415 such a construct is unspecified, and portable applications shall parenthesize
6416 properly all such usages.

6417 **system**(*expression*)
6418 Execute the command given by *expression* in a manner equivalent to the *system*( )
6419 function defined in the System Interfaces volume of IEEE Std. 1003.1-200x and
6420 return the exit status of the command.

6421 All forms of **getline** shall return 1 for successful input, zero for end-of-file, and –1 for an error.

6422 Where strings are used as the name of a file or pipeline, the application shall ensure that the
6423 strings are textually identical. The terminology ‘‘same string value’’ implies that ‘‘equivalent
6424 strings’’, even those that differ only by <space> characters, represent different files.

6425 **User-Defined Functions**

6426 The *awk* language also provides user-defined functions. Such functions can be defined as:

6427 `function` *`name`*`([`*`parameter, ...`*`]) { `*`statements`*` }`

6428 A function can be referred to anywhere in an *awk* program; in particular, its use can precede its
6429 definition. The scope of a function is global.

6430 Function parameters, if present, can be either scalars or arrays; the behavior is undefined if an
6431 array name is passed as a parameter that the function uses as a scalar, or if a scalar expression is
6432 passed as a parameter that the function uses as an array. Function parameters shall be passed by
6433 value if scalar and by reference if array name.

6434 The number of parameters in the function definition need not match the number of parameters
6435 in the function call. Excess formal parameters can be used as local variables. If fewer arguments
6436 are supplied in a function call than are in the function definition, the extra parameters that are
6437 used in the function body as scalars shall evaluate to the uninitialized value until they are
6438 otherwise initialized, and the extra parameters that are used in the function body as arrays shall
6439 be treated as uninitialized arrays where each element evaluates to the uninitialized value until
6440 otherwise initialized.

6441 When invoking a function, no white space can be placed between the function name and the
6442 opening parenthesis. Function calls can be nested and recursive calls can be made upon
6443 functions. Upon return from any nested or recursive function call, the values of all of the calling
6444 function’s parameters shall be unchanged, except for array parameters passed by reference. The
6445 **return** statement can be used to return a value. If a **return** statement appears outside of a
6446 function definition, the behavior is undefined.

6447 In the function definition, <newline> characters shall be optional before the opening brace and
6448 after the closing brace. Function definitions can appear anywhere in the program where a
6449 *pattern-action* pair is allowed.

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *awk* programs. The general conventions for this style of grammar are described in Section 1.10 (on page 2223). A valid program can be represented as the non-terminal symbol *program* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

```

This grammar has several ambiguities that shall be resolved as follows:

- Operator precedence and associativity shall be as described in Table 4-1 (on page 2370).
- In case of ambiguity, an **else** shall be associated with the most immediately preceding **if** that would satisfy the grammar.
- In some contexts, a slash (`'/'`) that is used to surround an ERE could also be the division operator. This shall be resolved in such a way that wherever the division operator could appear, a slash is assumed to be the division operator. (There is no unary division operator.)

One convention that might not be obvious from the formal grammar is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without backslashes can follow a comma, an open brace, logical AND operator ("&&"), logical OR operator ("||"), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print  $1,
         $2 }
```

Lexical Conventions

The lexical conventions for *awk* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *awk* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the number sign character and terminated by, but excluding the next occurrence of, a <newline> character. Comments shall have no effect, except to delimit lexical tokens.
3. The <newline> character shall be recognized as the token **NEWLINE**.
4. A backslash character immediately followed by a <newline> character shall have no effect.
5. The token **STRING** shall represent a string constant. A string constant shall begin with the character `'"'`. Within a string constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in Table 4-2 (on page 2376) shall be recognized. A <newline> character shall not occur within a string constant. A string constant shall be terminated by the first unescaped occurrence of the character `'"'` after the one that begins the string constant. The value of the string shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting `'"'` characters.
6. The token **ERE** represents an extended regular expression constant. An ERE constant shall begin with the slash character. Within an ERE constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation. In addition, the escape sequences in Table 4-2 (on page 2376) shall be recognized. The application shall ensure that a <newline> character does not occur within an ERE constant. An ERE constant shall be terminated by the first unescaped occurrence of the slash character after the one that begins the ERE constant. The extended regular expression represented by the ERE constant shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting slash characters.

7. A <blank> character shall have no effect, except to delimit lexical tokens or within **STRING** or **ERE** tokens.

8. The token **NUMBER** shall represent a numeric constant. Its form and numeric value shall be equivalent to either of the tokens **floating-constant** or **integer-constant** as specified by the ISO C standard, with the following exceptions:

   a. An integer constant cannot begin with 0x or include the hexadecimal digits `'a'`, `'b'`, `'c'`, `'d'`, `'e'`, `'f'`, `'A'`, `'B'`, `'C'`, `'D'`, `'E'`, or `'F'`.

   b. The value of an integer constant beginning with 0 shall be taken in decimal rather than octal.

   c. An integer constant cannot include a suffix (`'u'`, `'U'`, `'l'`, or `'L'`).

   d. A floating constant cannot include a suffix (`'f'`, `'F'`, `'l'`, or `'L'`).

   If the value is too large or too small to be representable, the behavior is undefined.

9. A sequence of underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set), beginning with an underscore or alphabetic, shall be considered a word.

10. The following words are keywords that shall be recognized as individual tokens; the name of the token is the same as the keyword:

BEGIN	**delete**	**END**	**function**	**in**	**printf**
break	**do**	**exit**	**getline**	**next**	**return**
continue	**else**	**for**	**if**	**print**	**while**

11. The following words are names of built-in functions and shall be recognized as the token **BUILTIN_FUNC_NAME**:

atan2	**gsub**	**log**	**split**	**sub**	**toupper**
close	**index**	**match**	**sprintf**	**substr**	
cos	**int**	**rand**	**sqrt**	**system**	
exp	**length**	**sin**	**srand**	**tolower**	

    The above-listed keywords and names of built-in functions are considered reserved words.

12. The token **NAME** shall consist of a word that is not a keyword or a name of a built-in function and is not followed immediately (without any delimiters) by the `'('` character.

13. The token **FUNC_NAME** shall consist of a word that is not a keyword or a name of a built-in function, followed immediately (without any delimiters) by the `'('` character. The `'('` character shall not be included as part of the token.

14. The following two-character sequences shall be recognized as the named tokens:

Token Name	Sequence	Token Name	Sequence
ADD_ASSIGN	+=	**NO_MATCH**	!~
SUB_ASSIGN	–=	**EQ**	==
MUL_ASSIGN	*=	**LE**	<=
DIV_ASSIGN	/=	**GE**	>=
MOD_ASSIGN	%=	**NE**	!=
POW_ASSIGN	^=	**INCR**	++
OR	||	**DECR**	––
AND	&&	**APPEND**	>>

15. The following single characters shall be recognized as tokens whose names are the character:

    ```
    <newline> { } ( ) [ ] , ; + – * % ^ ! > < | ? : ~ $ =
    ```

There is a lexical ambiguity between the token **ERE** and the tokens `'//'` and **DIV_ASSIGN**. When an input sequence begins with a slash character in any syntactic context where the token `'//'` or **DIV_ASSIGN** could appear as the next token in a valid program, the longer of those two tokens that can be recognized shall be recognized. In any other syntactic context where the token **ERE** could appear as the next token in a valid program, the token **ERE** shall be recognized.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

The exit status can be altered within the program by using an **exit** expression.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *awk* shall write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid *awk* program (as specified in the EXTENDED DESCRIPTION section), the behavior is undefined.

APPLICATION USAGE

The **index**, **length**, **match**, and **substr** functions should not be confused with similar functions in the ISO C standard; the *awk* versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

EXAMPLES

The *awk* program specified in the command line is most easily specified within single-quotes (for example, *'program'*) for applications using *sh*, because *awk* programs commonly contain characters that are special to the shell, including double-quotes. In the cases where an *awk* program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '//'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with *quote:*.

The following are examples of simple *awk* programs:

1. Write to the standard output all input lines for which field 3 is greater than 5:

   ```
   $3 > 5
   ```

2. Write every tenth line:

   ```
   (NR % 10) == 0
   ```

3. Write any line with a substring matching the regular expression:

   ```
   /(G|D)(2[0–9][[:alpha:]]*)/
   ```

4. Print any line with a substring containing a 'G' or 'D', followed by a sequence of digits and characters. This example uses character classes **digit** and **alpha** to match language-independent digit and alphabetic characters respectively:

```
/(G|D)([[:digit:][:alpha:]]*)/
```

5. Write any line in which the second field matches the regular expression and the fourth field does not:

```
$2 ~ /xyz/ && $4 !~ /xyz/
```

6. Write any line in which the second field contains a backslash:

```
$2 ~ /\\/
```

7. Write any line in which the second field contains a backslash. Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression:

```
$2 ~ "\\\\"
```

8. Write the second to the last and the last field in each line. Separate the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
```

9. Write the line number and number of fields in each line. The three strings representing the line number, the colon, and the number of fields are concatenated and that string is written to standard output:

```
{print NR ":" NF}
```

10. Write lines longer than 72 characters:

```
length($0) > 72
```

11. Write first two fields in opposite order separated by the **OFS**:

```
{ print $2, $1 }
```

12. Same, with input fields separated by comma or <space> and <tab> characters, or both:

```
BEGIN { FS = ",[ \t]*|[ \t]+" }
      { print $2, $1 }
```

13. Add up first column, print sum, and average:

```
      {s += $1 }
END   {print "sum is ", s, " average is", s/NR}
```

14. Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

15. Write all lines between occurrences of the strings **start** and **stop**:

```
/start/, /stop/
```

16. Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

17. Simulate *echo:*

```
BEGIN  {
        for (i = 1; i < ARGC; ++i)
        printf("%s%s", ARGV[i], i==ARGC-1?"\n":" ")
```

```
}
```

18. Write the path prefixes contained in the *PATH* environment variable, one per line:

```
BEGIN  {
        n = split (ENVIRON["PATH"], path, ":")
        for (i = 1; i <= n; ++i)
        print path[i]
}
```

19. If there is a file named **input** containing page headers of the form:

```
   Page #
```

and a file named **program** that contains:

```
/Page/   { $2 = n++; }
         { print }
```

then the command line:

```
awk –f program n=5 input
```

prints the file **input**, filling in page numbers starting at 5.

RATIONALE

The ISO POSIX-2 standard description is based on the new *awk*, ''nawk'', (see the referenced *The AWK Programming Language*), which introduced a number of new features to the historical *awk*:

1. New keywords: **delete**, **do**, **functin**, **return**
2. New built-in functions: **atan2**, **close**, **cos**, **gsub**, **match**, **rand**, **sin**, **srand**, **sub**, **system**
3. New predefined variables: **FNR**, **ARGC**, **ARGV**, **RSTART**, **RLENGTH**, **SUBSEP**
4. New expression operators: **?**, **:**, **„**, **^**
5. The **FS** variable and the third argument to **split**, now treated as extended regular expressions.
6. The operator precedence, changed to more closely match the C language. Two examples of code that operate differently are:

```
while ( n /= 10 > 1) ...
if (!"wk" ~ /bwk/) ...
```

Several features have been added based on newer implementations of *awk:*

- Multiple instances of **–f** *progfile* are permitted
- The new option **–v** *assignment*
- The new predefined variable **ENVIRON**
- New built-in functions **toupper**, and **tolower**
- More formatting capabilities are added to **printf** to match the ISO C standard

The overall *awk* syntax has always been based on the C language, with a few features from the shell command language and other sources. Because of this, it is not completely compatible with any other language, which has caused confusion for some users. It is not the intent of the standard developers to address such issues. IEEE Std. 1003.1-200x has made a few relatively minor changes toward making the language more compatible with the C language as specified by the ISO C standard; most of these changes are based on similar changes in recent

implementations, as described above. There remain several C-language conventions that are not in *awk*. One of the notable ones is the comma operator, which is commonly used to specify multiple expressions in the C language **for** statement. Also, there are various places where *awk* is more restrictive than the C language regarding the type of expression that can be used in a given context. These limitations are due to the different features that the *awk* language does provide.

Regular expressions in *awk* have been extended somewhat from historical implementations to make them a pure superset of extended regular expressions, as defined by IEEE Std. 1003.1-200x (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.4, Extended Regular Expressions). The main extensions are internationalization features and interval expressions. Historical implementations of *awk* have long supported backslash escape sequences as an extension to extended regular expressions, and this extension has been retained despite inconsistency with other utilities. The number of escape sequences recognized in both extended regular expressions and strings has varied (generally increasing with time) among implementations. The set specified by IEEE Std. 1003.1-200x includes most sequences known to be supported by popular implementations and by the ISO C standard. One sequence that is not supported is hexadecimal value escapes beginning with `'\x'`. This would allow values expressed in more than 9 bits to be used within *awk* as in the ISO C standard. However, because this syntax has a non-deterministic length, it does not permit the subsequent character to be a hexadecimal digit. This limitation can be dealt with in the C language by the use of lexical string concatenation. In the *awk* language, concatenation could also be a solution for strings, but not for extended regular expressions (either lexical ERE tokens or strings used dynamically as regular expressions). Because of this limitation, the feature has not been added to IEEE Std. 1003.1-200x.

When a string variable is used in a context where an extended regular expression normally appears (where the lexical token ERE is used in the grammar) the string does not contain the literal slashes.

Some versions of *awk* allow the form:

```
func name(args, ... ) { statements }
```

This has been deprecated by the authors of the language, who asked that it not be included in IEEE Std. 1003.1-200x.

Historical implementations of *awk* produce an error if a **next** statement is executed in a **BEGIN** action, and cause *awk* to terminate if a **next** statement is executed in an **END** action. This behavior has not been documented, and it was not believed that it was necessary to standardize it.

The specification of conversions between string and numeric values is much more detailed than in the documentation of historical implementations or in the referenced *The AWK Programming Language*. Although most of the behavior is designed to be intuitive, the details are necessary to ensure compatible behavior from different implementations. This is especially important in relational expressions since the types of the operands determine whether a string or numeric comparison is performed. From the perspective of an application writer, it is usually sufficient to expect intuitive behavior and to force conversions (by adding zero or concatenating a null string) when the type of an expression does not obviously match what is needed. The intent has been to specify historical practice in almost all cases. The one exception is that, in historical implementations, variables and constants maintain both string and numeric values after their original value is converted by any use. This means that referencing a variable or constant can have unexpected side effects. For example, with historical implementations the following program:

```
{
    a = "+2"
```

```
        b = 2
        if (NR % 2)
            c = a + b
        if (a == b)
            print "numeric comparison"
        else
            print "string comparison"
    }
```

would perform a numeric comparison (and output numeric comparison) for each odd-numbered line, but perform a string comparison (and output string comparison) for each even-numbered line. IEEE Std. 1003.1-200x ensures that comparisons will be numeric if necessary. With historical implementations, the following program:

```
BEGIN {
    OFMT = "%e"
    print 3.14
    OFMT = "%f"
    print 3.14
}
```

would output `"3.140000e+00"` twice, because in the second **print** statement the constant `"3.14"` would have a string value from the previous conversion. IEEE Std. 1003.1-200x requires that the output of the second **print** statement be `"3.140000"`. The behavior of historical implementations was seen as too unintuitive and unpredictable.

It was pointed out that with the rules contained in early drafts, the following script would print nothing:

```
BEGIN {
    y[1.5] = 1
    OFMT = "%e"
    print y[1.5]
}
```

Therefore, a new variable, **CONVFMT**, was introduced. The **OFMT** variable is now restricted to affecting output conversions of numbers to strings and **CONVFMT** is used for internal conversions, such as comparisons or array indexing. The default value is the same as that for **OFMT**, so unless a program changes **CONVFMT** (which no historical program would do), it will receive the historical behavior associated with internal string conversions.

The POSIX *awk* lexical and syntactic conventions are specified more formally than in other sources. Again the intent has been to specify historical practice. One convention that may not be obvious from the formal grammar as in other verbal descriptions is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without backslashes can follow a comma, an open brace, a logical AND operator (`"&&"`), a logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print $1,
        $2 }
```

The requirement that *awk* add a trailing <newline> character to the program argument text is to simplify the grammar, making it match a text file in form. There is no way for an application or test suite to determine whether a literal <newline> is added or whether *awk* simply acts as if it did.

IEEE Std. 1003.1-200x requires several changes from historical implementations in order to support internationalization. Probably the most subtle of these is the use of the decimal-point character, defined by the *LC_NUMERIC* category of the locale, in representations of floating-point numbers. This locale-specific character is used in recognizing numeric input, in converting between strings and numeric values, and in formatting output. However, regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments). This is essentially the same convention as the one used in the ISO C standard. The difference is that the C language includes the *setlocale*( ) function, which permits an application to modify its locale. Because of this capability, a C application begins executing with its locale set to the C locale, and only executes in the environment-specified locale after an explicit call to *setlocale*( ). However, adding such an elaborate new feature to the *awk* language was seen as inappropriate for IEEE Std. 1003.1-200x. It is possible to execute an *awk* program explicitly in any desired locale by setting the environment in the shell.

The undefined behavior resulting from NULs in extended regular expressions allows future extensions for the GNU *gawk* program to process binary data.

The behavior in the case of invalid *awk* programs (including lexical, syntactic, and semantic errors) is undefined because it was considered overly limiting on implementations to specify. In most cases such errors can be expected to produce a diagnostic and a non-zero exit status. However, some implementations may choose to extend the language in ways that make use of certain invalid constructs. Other invalid constructs might be deemed worthy of a warning, but otherwise cause some reasonable behavior. Still other constructs may be very difficult to detect in some implementations. Also, different implementations might detect a given error during an initial parsing of the program (before reading any input files) while others might detect it when executing the program after reading some input. Implementors should be aware that diagnosing errors as early as possible and producing useful diagnostics can ease debugging of applications, and thus make an implementation more usable.

The unspecified behavior from using multi-character **RS** values is to allow possible future extensions based on extended regular expressions used for record separators. Historical implementations take the first character of the string and ignore the others.

Unspecified behavior when *split*(*string*,*array*,<null>) is used is to allow a proposed future extension that would split up a string into an array of individual characters.

In the context of the **getline** function, equally good arguments for different precedences of the **|** and **<** operators can be made. Historical practice has been that:

```
getline < "a" "b"
```

is parsed as:

```
( getline < "a" ) "b"
```

although many would argue that the intent was that the file **ab** should be read. However:

```
getline < "x" + 1
```

parses as:

```
getline < ( "x" + 1 )
```

Similar problems occur with the **|** version of **getline**, particularly in combination with **$**. For example:

```
$"echo hi" | getline
```

(This situation is particularly problematic when used in a **print** statement, where the **|getline** part might be a redirection of the **print**.)

Since in most cases such constructs are not (or at least should not) be used (because they have a natural ambiguity for which there is no conventional parsing), the meaning of these constructs has been made explicitly unspecified. (The effect is that a portable application that runs into the problem must parenthesize to resolve the ambiguity.) There appeared to be few if any actual uses of such constructs.

Grammars can be written that would cause an error under these circumstances. Where backwards compatibility is not a large consideration, implementors may wish to use such grammars.

Some historical implementations have allowed some built-in functions to be called without an argument list, the result being a default argument list chosen in some ‘‘reasonable’’ way. Use of **length** as a synonym for **length($0)** is the only one of these forms that is thought to be widely known or widely used; this particular form is documented in various places (for example, most historical *awk* reference pages, although not in the referenced *The AWK Programming Language*) as legitimate practice. With this exception, default argument lists have always been undocumented and vaguely defined, and it is not at all clear how (or if) they should be generalized to user-defined functions. They add no useful functionality and preclude possible future extensions that might need to name functions without calling them. Not standardizing them seems the simplest course. The standard developers considered that **length** merited special treatment, however, since it has been documented in the past and sees possibly substantial use in historical programs. Accordingly, this usage has been made legitimate, but Issue 5 removed the obsolescent marking for XSI-conforming implementations and many otherwise conforming applications depend on this feature.

In **sub** and **gsub**, if *repl* is a string literal (the lexical token **STRING**), then two consecutive backslash characters should be used in the string to ensure a single backslash will precede the ampersand when the resultant string is passed to the function. (For example, to specify one literal ampersand in the replacement string, use **gsub**(**ERE**, `"\\&"`).)

Historically the only special character in the *repl* argument of **sub** and **gsub** string functions was the ampersand (`'&'`) character and preceding it with the backslash character was used to turn off its special meaning.

The description in the ISO POSIX-2: 1993 standard introduced behavior such that the backslash character was another special character and it was unspecified whether there were any other special characters. This description introduced several portability problems, some of which are described below, and so it has been replaced with the more historical description. Some of the problems include:

- Historically, to create the replacement string, a script could use **gsub**(**ERE**, `"\\&"`), but with the ISO POSIX-2: 1993 standard wording, it was necessary to use **gsub**(**ERE**, `"\\\\&"`). Backslash characters are doubled here because all string literals are subject to lexical analysis, which would reduce each pair of backslash characters to a single backslash before being passed to **gsub**.
- Since it was unspecified what the special characters were, for portable scripts to guarantee that characters are printed literally, each character had to be preceded with a backslash. (For example, a portable script had to use **gsub**(**ERE**, `"\\h\\i"`) to produce a replacement string of `"hi"`.)

The description for comparisons in the ISO POSIX-2: 1993 standard did not properly describe historical practice because of the way numeric strings are compared as numbers. The current rules cause the following code:

```
7134        if (0 == "000")
7135            print "strange, but true"
7136        else
7137            print "not true"
```

to do a numeric comparison, causing the **if** to succeed. It should be intuitively obvious that this is incorrect behavior, and indeed, no historical implementation of *awk* actually behaves this way.

To fix this problem, the definition of *numeric string* was enhanced to include only those values obtained from specific circumstances (mostly external sources) where it is not possible to determine unambiguously whether the value is intended to be a string or a numeric.

Variables that are assigned to a numeric string shall also be treated as a numeric string. (For example, the notion of a numeric string can be propagated across assignments.) In comparisons, all variables having the uninitialized value are to be treated as a numeric operand evaluating to the numeric value zero.

Uninitialized variables include all types of variables including scalars, array elements, and fields. The definition of an uninitialized value in **Variables and Special Variables** (on page 2373) is necessary to describe the value placed on uninitialized variables and on fields that are valid (for example, **< $NF**) but have no characters in them and to describe how these variables are to be used in comparisons. A valid field, such as **$1**, that has no characters in it can be obtained by from an input line of `"\t\t"` when **FS='\t'**. Historically, the comparison (**$1**<10) was done numerically after evaluating **$1** to the value zero.

The phrase ‘‘... also shall have the numeric value of the numeric string’’ was removed from several sections of the ISO POSIX-2: 1993 standard because is specifies an unnecessary implementation detail. It is not necessary for IEEE Std. 1003.1-200x to specify that these objects be assigned two different values. It is only necessary to specify that these objects may evaluate to two different values depending on context.

The description of numeric string processing is based on the behavior of the *atof*( ) function in the ISO C standard. While it is not a requirement for an implementation to use this function, many historical implementations of *awk* do. In the ISO C standard, floating-point constants use a period as a decimal point character for the language itself, independent of the current locale, but the *atof*( ) function and the associated *strtod*( ) function use the decimal point character of the current locale when converting strings to numeric values. Similarly in *awk*, floating point constants in an *awk* script use a period independent of the locale, but input strings use the decimal point character of the locale.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 4, Version 2

The EXAMPLES section is corrected as follows:

- In Example 10, the braces are removed.
- In Example 17, the invocation of **printf** is corrected.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The *awk* utility is aligned with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

basename — return non-directory portion of a path name

SYNOPSIS

```
basename string [suffix]
```

DESCRIPTION

The *string* operand shall be treated as a path name, as defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.268, Path Name. The string *string* shall be converted to the file name corresponding to the last path name component in *string* and then the suffix string *suffix*, if present, shall be removed. This shall be done by performing actions equivalent to the following steps in order:

1. If *string* is a null string, it is unspecified whether the resulting string is `'.'` or a null string. In either case, skip steps 2 through 6.
2. If *string* is `"//"`, it is implementation-defined whether steps 3 to 6 are skipped or processed.
3. If *string* consists entirely of slash characters, *string* shall be set to a single slash character. In this case, skip steps 4 to 6.
4. If there are any trailing slash characters in *string*, they shall be removed.
5. If there are any slash characters remaining in *string*, the prefix of *string* up to and including the last slash character in *string* shall be removed.
6. If the *suffix* operand is present, is not identical to the characters remaining in *string*, and is identical to a suffix of the characters remaining in *string*, the suffix *suffix* shall be removed from *string*. Otherwise, *string* is modified by this step. It shall not be considered an error if *suffix* is not found in *string*.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

string A string.

suffix A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *basename*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *basename* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of *pathname* specifies implementation-defined behavior for path names starting with two slash characters. Therefore, applications shall not arbitrarily add slashes to the beginning of a path name unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES

If the string *string* is a valid path name:

```
$(basename "string")
```

produces a file name that could be used to open the file named by *string* in the directory returned by:

```
$(dirname "string")
```

If the string *string* is not a valid path name, the same algorithm is used, but the result need not be a valid file name. The *basename* utility is not expected to make any judgements about the validity of *string* as a path name; it just follows the specified algorithm to produce a result string.

The following shell script compiles **/usr/src/cmd/cat.c** and moves the output to a file named **cat** in the current directory when invoked with the argument **/usr/src/cmd/cat** or with the argument **/usr/src/cmd/cat.c**:

```
c99 $(dirname "$1")/$(basename "$1" .c).c
mv a.out $(basename "$1" .c)
```

RATIONALE

The behaviors of *basename* and *dirname* have been coordinated so that when *string* is a valid path name:

`$(basename "`*`string`*`")`

would be a valid file name for the file in the directory:

`$(dirname "`*`string`*`")`

This would not work for the early proposal versions of these utilities due to the way it specified handling of trailing slashes.

Since the definition of *pathname* specifies implementation-defined behavior for path names starting with two slash characters, this volume of IEEE Std. 1003.1-200x specifies similar implementation-defined behavior for the *basename* and *dirname* utilities.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

IEEE PASC Interpretation 1003.2 #164 has been applied.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

7292 **NAME**

7293 batch — schedule commands to be executed in a batch queue

7294 **SYNOPSIS**

7295 UP *batch*

7296

7297 **DESCRIPTION**

7298 The *batch* utility shall read commands from standard input and schedule them for execution in a
7299 batch queue. It shall be the equivalent of the command:

7300 `at -q b -m now`

7301 where queue *b* is a special *at* queue, specifically for batch jobs. Batch jobs shall be submitted to
7302 the batch queue with no time constraints and shall be run by the system using algorithms, based
7303 on unspecified factors, that may vary with each invocation of *batch*.

7304 XSI Users are permitted to use *batch* if their name appears in the file **/usr/lib/cron/at.allow**. If that file
7305 does not exist, the file **/usr/lib/cron/at.deny** is checked to determine whether the user should be
7306 denied access to *batch*. If neither file exists, only a process with the appropriate privileges is
7307 allowed to submit a job. If only **at.deny** exists and is empty, global usage is permitted. The
7308 **at.allow** and **at.deny** files consist of one user name per line.

7309 **OPTIONS**

7310 None.

7311 **OPERANDS**

7312 None.

7313 **STDIN**

7314 The standard input shall be a text file consisting of commands acceptable to the shell command
7315 language described in Chapter 2 (on page 2235).

7316 **INPUT FILES**

7317 XSI The text files **/usr/lib/cron/at.allow** and **/usr/lib/cron/at.deny** contain user names, one per line, of
7318 users who are, respectively, authorized or denied access to the *at* and *batch* utilities.

7319 **ENVIRONMENT VARIABLES**

7320 The following environment variables shall affect the execution of *batch*:

7321 *LANG* Provide a default value for the internationalization variables that are unset or null.
7322 If *LANG* is unset or null, the corresponding value from the implementation-
7323 defined default locale shall be used. If any of the internationalization variables
7324 contains an invalid setting, the utility shall behave as if none of the variables had
7325 been defined.

7326 *LC_ALL* If set to a non-empty string value, override the values of all the other
7327 internationalization variables.

7328 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
7329 characters (for example, single-byte as opposed to multi-byte characters in
7330 arguments and input files).

7331 *LC_MESSAGES*
7332 Determine the locale that should be used to affect the format and contents of
7333 diagnostic messages written to standard error and informative messages written to
7334 standard output.

7335 *LC_TIME* Determine the format and contents for date and time strings written by *batch*.

7336 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

7337 *SHELL* Determine the name of a command interpreter to be used to invoke the at-job. If
7338 the variable is unset or null, *sh* shall be used. If it is set to a value other than a name
7339 for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use
7340 the login shell from the user database; any of the preceding accompanied by a
7341 warning diagnostic about which was chosen.

7342 *TZ* Determine the timezone. The job shall be submitted for execution at the time
7343 specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ*
7344 variable. If *timespec* specifies a timezone, it overrides *TZ*. If *timespec* does not
7345 specify a timezone and *TZ* is unset or null, an unspecified default timezone shall
7346 be used.

7347 **ASYNCHRONOUS EVENTS**

7348 Default.

7349 **STDOUT**

7350 When standard input is a terminal, prompts of unspecified format for each line of the user input
7351 described in the STDIN section may be written to standard output.

7352 **STDERR**

7353 The following shall be written to standard error when a job has been successfully submitted:

7354 `"job %s at %s\n", `*`at_job_id`*`, <`*`date`*`>`

7355 where *date* shall be equivalent in format to the output of:

7356 `date +"%a %b %e %T %Y"`

7357 The date and time written shall be adjusted so that they appear in the timezone of the user (as
7358 determined by the *TZ* variable).

7359 Neither this, nor warning messages concerning the selection of the command interpreter, are
7360 considered a diagnostic that changes the exit status.

7361 Diagnostic messages, if any, shall be written to standard error.

7362 **OUTPUT FILES**

7363 None.

7364 **EXTENDED DESCRIPTION**

7365 None.

7366 **EXIT STATUS**

7367 The following exit values shall be returned:

7368 0 Successful completion.

7369 >0 An error occurred.

7370 **CONSEQUENCES OF ERRORS**

7371 The job shall not be scheduled.

APPLICATION USAGE

It may be useful to redirect standard output within the specified commands.

EXAMPLES

1. This sequence can be used at a terminal:

```
batch
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
batch <<! diff file1 file2 2>&1 >outfile | mailx mygroup !
```

RATIONALE

Early proposals described *batch* in a manner totally separated from *at*, even though the historical model treated it almost as a synonym for *at* −**qb**. A number of features were added to list and control batch work separately from those in *at*. Upon further reflection, it was decided that the benefit of this did not merit the change to the historical interface.

The −**m** option was included on the equivalent *at* command because it is historical practice to mail results to the submitter, even if all job-produced output is redirected. As explained in the RATIONALE for *at*, the **now** keyword submits the job for immediate execution (after scheduling delays), despite some historical systems where *at* **now** would have been considered an error.

FUTURE DIRECTIONS

None.

at

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized and separated from the *at* description.

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The NAME is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

bc — arbitrary-precision arithmetic language

SYNOPSIS

`bc [-l] [file ...]`

DESCRIPTION

The *bc* utility shall implement an arbitrary precision calculator. It shall take input from any files given, then read from the standard input. If the standard input and standard output to *bc* are attached to a terminal, the invocation of *bc* shall be considered to be *interactive*, causing behavioral constraints described in the following sections.

OPTIONS

The *bc* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–l (The letter ell.) Define the math functions and initialize *scale* to 20, instead of the default zero; see the EXTENDED DESCRIPTION section.

OPERANDS

The following operand shall be supported:

file A path name of a text file containing *bc* program statements. After all *file*s have been read, *bc* shall read the standard input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files containing a sequence of comments, statements, and function definitions that shall be executed as they are read.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bc*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of the *bc* utility shall be controlled by the program read, and consist of zero or more lines containing the value of all executed expressions without assignments. The radix and precision of the output shall be controlled by the values of the **obase** and **scale** variables; see the EXTENDED DESCRIPTION section.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for *bc* programs. The general conventions for this style of grammar are described in Section 1.10 (on page 2223). A valid program can be represented as the non-terminal symbol **program** in the grammar. This formal syntax shall take precedence over the text syntax description.

```

                      | Obase
                      ;
```

Lexical Conventions in bc

The lexical conventions for *bc* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *bc* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the two adjacent characters "/*" and terminated by the next occurrence of the two adjacent characters "*/". Comments shall have no effect except to delimit lexical tokens.
3. The <newline> character shall be recognized as the token **NEWLINE**.
4. The token **STRING** shall represent a string constant; it shall consist of any characters beginning with the double-quote character ('"') and terminated by another occurrence of the double-quote character. The value of the string is the sequence of all characters between, but not including, the two double-quote characters. All characters shall be taken literally from the input, and there is no way to specify a string containing a double-quote character. The length of the value of each string shall be limited to {BC_STRING_MAX} bytes.
5. A <blank> character shall have no effect except as an ordinary character if it appears within a **STRING** token, or to delimit a lexical token other than **STRING**.

6. The combination of a backslash character immediately followed by a <newline> character shall have no effect other than to delimit lexical tokens with the following exceptions:

   - It shall be interpreted as the character sequence "\<newline>" in **STRING** tokens.
   - It shall be ignored as part of a multi-line **NUMBER** token.

7. The token **NUMBER** shall represent a numeric constant. It shall be recognized by the following grammar:

```
NUMBER  : integer
        | '.' integer
        | integer '.'
        | integer '.' integer
        ;

integer : digit
        | integer digit
        ;

digit   : 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
        | 8 | 9 | A | B | C | D | E | F
        ;
```

8. The value of a **NUMBER** token shall be interpreted as a numeral in the base specified by the value of the internal register **ibase** (described below). Each of the **digit** characters shall have the value from 0 to 15 in the order listed here, and the period character shall represent the radix point. The behavior is undefined if digits greater than or equal to the value of **ibase** appear in the token. However, note the exception for single-digit values being assigned to **ibase** and **obase** themselves, in **Operations in bc** (on page 2412).

9. The following keywords shall be recognized as tokens:

auto	**ibase**	**length**	**return**	**while**
break	**if**	**obase**	**scale**	
define	**for**	**quit**	**sqrt**	

10. Any of the following characters occurring anywhere except within a keyword shall be recognized as the token **LETTER**:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
```

11. The following single-character and two-character sequences shall be recognized as the token **ASSIGN_OP**:

```
=    +=    -=    *=    /=    %=    ^=
```

12. If an '=' character, as the beginning of a token, is followed by a '-' character with no intervening delimiter, the behavior is undefined.

13. The following single-characters shall be recognized as the token **MUL_OP**:

```
*    /    %
```

14. The following single-character and two-character sequences shall be recognized as the token **REL_OP**:

```
==    <=    >=    !=    <    >
```

15. The following two-character sequences shall be recognized as the token **INCR_DECR**:

7622 `++ --`

7623 16. The following single characters shall be recognized as tokens whose names are the
7624 character:

7625 `<newline> ( ) , + - ; [ ] ^ { }`

7626 17. The token **EOF** is returned when the end of input is reached.

7627 **Operations in bc**

7628 There are three kinds of identifiers: ordinary identifiers, array identifiers, and function
7629 identifiers. All three types consist of single lowercase letters. Array identifiers shall be followed
7630 by square brackets ("`[]`"). An array subscript is required except in an argument or auto list.
7631 Arrays are singly dimensioned and can contain up to {BC_DIM_MAX} elements. Indexing shall
7632 begin at zero so an array is indexed from 0 to {BC_DIM_MAX}−1. Subscripts shall be truncated
7633 to integers. The application shall ensure that function identifiers are followed by parentheses,
7634 possibly enclosing arguments. The three types of identifiers do not conflict.

7635 The following table summarizes the rules for precedence and associativity of all operators.
7636 Operators on the same line shall have the same precedence; rows are in order of decreasing
7637 precedence.

7638 **Table 4-3** Operators in *bc*

7639

Operator	Associativity
`++, --`	N/A
`unary -`	N/A
`^`	Right to left
`*, /, %`	Left to right
`+, binary -`	Left to right
`=, +=, -=, *=, /=, %=, ^=`	Right to left
`==, <=, >=, !=, <, >`	None

7646

7647 Each expression or named expression has a *scale*, which is the number of decimal digits that
7648 shall be maintained as the fractional portion of the expression.

7649 *Named expressions* are places where values are stored. Named expressions shall be valid on the
7650 left side of an assignment. The value of a named expression shall be the value stored in the place
7651 named. Simple identifiers and array elements are named expressions; they have an initial value
7652 of zero and an initial scale of zero.

7653 The internal registers **scale**, **ibase**, and **obase** are all named expressions. The scale of an
7654 expression consisting of the name of one of these registers shall be zero; values assigned to any
7655 of these registers are truncated to integers. The **scale** register shall contain a global value used in
7656 computing the scale of expressions (as described below). The value of the register **scale** is
7657 limited to 0 ≤ **scale** ≤ {BC_SCALE_MAX} and shall have a default value of zero. The **ibase** and
7658 **obase** registers are the input and output number radix, respectively. The value of **ibase** shall be
7659 limited to:

7660 `2 ≤ ibase ≤ 16`

7661 The value of **obase** shall be limited to:

7662 `2 ≤ obase ≤ {BC_BASE_MAX}`

7663 When either **ibase** or **obase** is assigned a single **digit** value from the list in **Lexical Conventions**
7664 **in bc** (on page 2410), the value shall be assumed in hexadecimal. (For example, **ibase**=A sets to

base ten, regardless of the current **ibase** value.) Otherwise, the behavior is undefined when digits greater than or equal to the value of **ibase** appear in the input. Both **ibase** and **obase** shall have initial values of 10.

Internal computations shall be conducted as if in decimal, regardless of the input and output bases, to the specified number of decimal digits. When an exact result is not achieved, (for example, **scale**=0; 3.2 / 1) the result shall be truncated.

For all values of **obase** specified by this volume of IEEE Std. 1003.1-200x, *bc* shall output numeric values by performing each of the following steps in order:

1. If the value is less than zero, a hyphen (`'-'`) character shall be output.
2. One of the following is output, depending on the numerical value:
   - If the absolute value of the numerical value is greater than or equal to one, the integer portion of the value shall be output as a series of digits appropriate to **obase** (as described below) most significant digit first. The most significant non-zero digit shall be output next, followed by each successively less significant digit.
   - If the absolute value of the numerical value is less than one but greater than zero and the scale of the numerical value is greater than zero, it is unspecified whether the character 0 is output.
   - If the numerical value is zero, the character 0 shall be output.
3. If the scale of the value is greater than zero and the numeric value is not zero, a period character shall be output, followed by a series of digits appropriate to **obase** (as described below) representing the most significant portion of the fractional part of the value. If *s* represents the scale of the value being output, the number of digits output shall be *s* if **obase** is 10, less than or equal to *s* if **obase** is greater than 10, or greater than or equal to *s* if **obase** is less than 10. For **obase** values other than 10, this should be the number of digits needed to represent a precision of 10^s.

For **obase** values from 2 to 16, valid digits are the first **obase** of the single characters:

```
0 1 2 3 4 5 6 7 8 9 A B C D E F
```

which represent the values zero to 15, inclusive, respectively.

For bases greater than 16, each digit shall be written as a separate multi-digit decimal number. Each digit except the most significant fractional digit shall be preceded by a single <space> character. For bases from 17 to 100, *bc* shall write two-digit decimal numbers; for bases from 101 to 1 000, three-digit decimal strings, and so on. For example, the decimal number 1 024 in base 25 would be written as:

```
Δ01Δ15Δ24
```

in base 125, as:

```
Δ008Δ024
```

Very large numbers shall be split across lines with 70 characters per line in the POSIX locale; other locales may split at different character boundaries. Lines that are continued shall end with a backslash (`'\'`).

A function call shall consist of a function name followed by parentheses containing a comma-separated list of expressions, which are the function arguments. A whole array passed as an argument shall be specified by the array name followed by empty square brackets. All function arguments shall be passed by value. As a result, changes made to the formal parameters shall have no effect on the actual arguments. If the function terminates by executing a **return**

statement, the value of the function shall be the value of the expression in the parentheses of the **return** statement or shall be zero if no expression is provided or if there is no **return** statement.

The result of **sqrt**(*expression*) shall be the square root of the expression. The result shall be truncated in the least significant decimal place. The scale of the result shall be the scale of the expression or the value of **scale**, whichever is larger.

The result of **length**(*expression*) shall be the total number of significant decimal digits in the expression. The scale of the result shall be zero.

The result of **scale**(*expression*) shall be the scale of the expression. The scale of the result shall be zero.

A numeric constant shall be an expression. The scale shall be the number of digits that follow the radix point in the input representing the constant, or zero if no radix point appears.

The sequence (*expression*) shall be an expression with the same value and scale as *expression*. The parentheses can be used to alter the normal precedence.

The semantics of the unary and binary operators are as follows:

–expression
: The result shall be the negative of the *expression*. The scale of the result shall be the scale of *expression*.

The unary increment and decrement operators shall not modify the scale of the named expression upon which they operate. The scale of the result shall be the scale of that named expression.

++named-expression
: The named expression shall be incremented by one. The result shall be the value of the named expression after incrementing.

––named-expression
: The named expression shall be decremented by one. The result shall be the value of the named expression after decrementing.

named-expression++
: The named expression shall be incremented by one. The result shall be the value of the named expression before incrementing.

named-expression––
: The named expression shall be decremented by one. The result shall be the value of the named expression before decrementing.

The exponentiation operator, circumflex (`'^'`), shall bind right to left.

expression^expression
: The result shall be the first *expression* raised to the power of the second *expression*. If the second expression is not an integer, the behavior is undefined. If *a* is the scale of the left expression and *b* is the absolute value of the right expression, the scale of the result shall be:

```
if b >= 0 min(a * b, max(scale, a)) if b < 0 scale
```

The multiplicative operators (`'*'`, `'/'`, `'%'`) shall bind left to right.

*expression*expression*
: The result shall be the product of the two expressions. If *a* and *b* are the scales of the two expressions, then the scale of the result shall be:

```
min(a+b,max(scale,a,b))
```

expression / *expression*

The result shall be the quotient of the two expressions. The scale of the result shall be the value of **scale**.

expression%*expression*

For expressions *a* and *b*, *a*%*b* shall be evaluated equivalent to the steps:

1. Compute *a* / *b* to current scale.
2. Use the result to compute:

   ```
   a – (a / b) * b
   ```

   to scale:

   ```
   max(scale + scale(b), scale(a))
   ```

The scale of the result shall be:

```
max(scale + scale(b), scale(a))
```

When **scale** is zero, the `'%'` operator is the mathematical remainder operator.

The additive operators (`'+'`, `'–'`) shall bind left to right.

expression+*expression*

The result shall be the sum of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

expression–*expression*

The result shall be the difference of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.

The assignment operators (`'='`, `"+="`, `"–="`, `"*="`, `"/="`, `"%="`, `"^="`) shall bind right to left.

named-expression=*expression*

This expression results in assigning the value of the expression on the right to the named expression on the left. The scale of both the named expression and the result shall be the scale of *expression*.

The compound assignment forms:

named-expression <*operator*>= *expression*

shall be equivalent to:

named-expression=*named-expression* <*operator*> *expression*

except that the *named-expression* shall be evaluated only once.

Unlike all other operators, the relational operators (`'<'`, `'>'`, `"<="`, `">="`, `"=="`, `"!="`) shall be only valid as the object of an **if**, **while**, or inside a **for** statement.

expression1<*expression2*

The relation shall be true if the value of *expression1* is strictly less than the value of *expression2*.

expression1>*expression2*

The relation shall be true if the value of *expression1* is strictly greater than the value of *expression2*.

expression1<=*expression2*
The relation shall be true if the value of *expression1* is less than or equal to the value of *expression2*.

expression1>=*expression2*
The relation shall be true if the value of *expression1* is greater than or equal to the value of *expression2*.

expression1==*expression2*
The relation shall be true if the values of *expression1* and *expression2* are equal.

expression1!=*expression2*
The relation shall be true if the values of *expression1* and *expression2* are unequal.

There are only two storage classes in *bc*, global and automatic (local). Only identifiers that are local to a function need be declared with the **auto** command. The arguments to a function shall be local to the function. All other identifiers are assumed to be global and available to all functions. All identifiers, global and local, have initial values of zero. Identifiers declared as auto shall be allocated on entry to the function and released on returning from the function. They therefore do not retain values between function calls. Auto arrays shall be specified by the array name followed by empty square brackets. On entry to a function, the old values of the names that appear as parameters and as automatic variables shall be pushed onto a stack. Until the function returns, reference to these names shall refer only to the new values.

References to any of these names from other functions that are called from this function also refer to the new value until one of those functions uses the same name for a local variable.

When a statement is an expression, unless the main operator is an assignment, execution of the statement shall write the value of the expression followed by a <newline> character.

When a statement is a string, execution of the statement shall write the value of the string.

Statements separated by semicolons or <newline> characters shall be executed sequentially. In an interactive invocation of *bc*, each time a <newline> character is read that satisfies the grammatical production:

```
input_item : semicolon_list NEWLINE
```

the sequential list of statements making up the **semicolon_list** shall be executed immediately and any output produced by that execution shall be written without any delay due to buffering.

In an **if** statement (**if**(*relation*) *statement*), the *statement* shall be executed if the relation is true.

The **while** statement (**while**(*relation*) *statement*) implements a loop in which the *relation* is tested; each time the *relation* is true, the *statement* shall be executed and the *relation* retested. When the *relation* is false, execution shall resume after *statement*.

A **for** statement(**for**(*expression*; *relation*; *expression*) *statement*) shall be the same as:

```
first-expression
while (relation) {
    statement
    last-expression
}
```

The application shall ensure that all three expressions are present.

The **break** statement shall cause termination of a **for** or **while** statement.

The **auto** statement (**auto** *identifier* **[**,*identifier***]** ...) shall cause the values of the identifiers to be pushed down. The identifiers can be ordinary identifiers or array identifiers. Array identifiers

shall be specified by following the array name by empty square brackets. The application shall ensure that the **auto** statement is the first statement in a function definition.

A **define** statement:

```
define LETTER ( opt_parameter_list ) {
    opt_auto_define_list
    statement_list
}
```

defines a function named **LETTER**. If a function named **LETTER** was previously defined, the **define** statement shall replace the previous definition. The expression:

```
LETTER ( opt_argument_list )
```

shall invoke the function named **LETTER**. The behavior is undefined if the number of arguments in the invocation does not match the number of parameters in the definition. Functions shall be defined before they are invoked. A function shall be considered to be defined within its own body, so recursive calls are valid. The values of numeric constants within a function shall be interpreted in the base specified by the value of the **ibase** register when the function is invoked.

The **return** statements (**return** and **return**(*expression*)) shall cause termination of a function, popping of its auto variables, and specification of the result of the function. The first form shall be equivalent to **return**(0). The value and scale of the result returned by the function shall be the value and scale of the expression returned.

The **quit** statement (**quit**) shall stop execution of a *bc* program at the point where the statement occurs in the input, even if it occurs in a function definition, or in an **if**, **for**, or **while** statement.

The following functions shall be defined when the **–l** option is specified:

s(*expression*)
: Sine of argument in radians.

c(*expression*)
: Cosine of argument in radians.

a(*expression*)
: Arctangent of argument.

l(*expression*)
: Natural logarithm of argument.

e(*expression*)
: Exponential function of argument.

j(*expression*, *expression*)
: Bessel function of integer order.

The scale of the result returned by these functions shall be the value of the **scale** register at the time the function is invoked. The value of the **scale** register after these functions have completed their execution shall be the same value it had upon invocation. The behavior is undefined if any of these functions is invoked with an argument outside the domain of the mathematical function.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

unspecified An error occurred.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *bc* shall write a diagnostic message to standard error and terminate without any further action.

In an interactive invocation of *bc*, the utility should print an error message and recover following any error in the input. In a non-interactive invocation of *bc*, invalid input causes undefined behavior.

APPLICATION USAGE

Automatic variables in *bc* do not work in exactly the same way as in either C or PL/1.

For historical reasons, the exit status from *bc* cannot be relied upon to indicate that an error has occurred. Returning zero after an error is possible. Therefore, *bc* should be used primarily by interactive users (who can react to error messages) or by application programs that can somehow validate the answers returned as not including error messages.

The *bc* utility always uses the period (`'.'`) character to represent a radix point, regardless of any decimal-point character specified as part of the current locale. In languages like C or *awk*, the period character is used in program source, so it can be portable and unambiguous, while the locale-specific character is used in input and output. Because there is no distinction between source and input in *bc*, this arrangement would not be possible. Using the locale-specific character in *bc*'s input would introduce ambiguities into the language; consider the following example in a locale with a comma as the decimal-point character:

```
define f(a,b) {
    ...
}
...
f(1,2,3)
```

Because of such ambiguities, the period character is used in input. Having input follow different conventions from output would be confusing in either pipeline usage or interactive usage, so the period is also used in output.

EXAMPLES

In the shell, the following assigns an approximation of the first ten digits of `'π'` to the variable *x*:

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

The following *bc* program prints the same approximation of `'π'`, with a label, to standard output:

```
scale = 10
"pi equals "
104348 / 33215
```

The following defines a function to compute an approximate value of the exponential function (note that such a function is predefined if the **–l** option is specified):

```
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
```

```
        for (i = 1; 1 == 1; i++){
            a = a*x
            b = b*i
            c = a/b
            if (c == 0) {
                 return(s)
            }
            s = s+c
        }
    }
```

The following prints approximate values of the exponential function of the first ten integers:

```
for (i = 1; i <= 10; ++i) {
    e(i)
}
```

RATIONALE

The *bc* utility is implemented historically as a front-end processor for *dc*; *dc* was not selected to be part of this volume of IEEE Std. 1003.1-200x because *bc* was thought to have a more intuitive programmatic interface. Current implementations that implement *bc* using *dc* are expected to be compliant.

The exit status for error conditions has been left unspecified for several reasons:

- The *bc* utility is used in both interactive and non-interactive situations. Different exit codes may be appropriate for the two uses.
- It is unclear when a non-zero exit should be given; divide-by-zero, undefined functions, and syntax errors are all possibilities.
- It is not clear what utility the exit status has.
- In the 4.3 BSD, System V, and Ninth Edition implementations, *bc* works in conjunction with *dc*. The *dc* utility is the parent, *bc* is the child. This was done to cleanly terminate *bc* if *dc* aborted.

The decision to have *bc* exit upon encountering an inaccessible input file is based on the belief that *bc file1 file2* is used most often when at least *file1* contains data/function declarations/initializations. Having *bc* continue with prerequisite files missing is probably not useful. There is no implication in the CONSEQUENCES OF ERRORS section that *bc* must check all its files for accessibility before opening any of them.

There was considerable debate on the appropriateness of the language accepted by *bc*. Several reviewers preferred to see either a pure subset of the C language or some changes to make the language more compatible with C. While the *bc* language has some obvious similarities to C, it has never claimed to be compatible with any version of C. An interpreter for a subset of C might be a very worthwhile utility, and it could potentially make *bc* obsolete. However, no such utility is known in historical practice, and it was not within the scope of this volume of IEEE Std. 1003.1-200x to define such a language and utility. If and when they are defined, it may be appropriate to include them in a future version of this volume of IEEE Std. 1003.1-200x. This left the following alternatives:

1. Exclude any calculator language from this volume of IEEE Std. 1003.1-200x.

   The consensus of the standard developers was that a simple programmatic calculator language is very useful for both applications and interactive users. The only arguments for excluding any calculator were that it would become obsolete if and when a C-compatible

one emerged, or that the absence would encourage the development of such a C-compatible one. These arguments did not sufficiently address the needs of current application writers.

2. Standardize the historical *dc*, possibly with minor modifications.

   The consensus of the standard developers was that *dc* is a fundamentally less usable language and that that would be far too severe a penalty for avoiding the issue of being similar to but incompatible with C.

3. Standardize the historical *bc*, possibly with minor modifications.

   This was the approach taken. Most of the proponents of changing the language would not have been satisfied until most or all of the incompatibilities with C were resolved. Since most of the changes considered most desirable would break historical applications and require significant modification to historical implementations, almost no modifications were made. The one significant modification that was made was the replacement of the historical *bc* assignment operators "=+", and so on, with the more modern "+=", and so on. The older versions are considered to be fundamentally flawed because of the lexical ambiguity in uses like *a*=–1.

   In order to permit implementations to deal with backwards compatibility as they see fit, the behavior of this one ambiguous construct was made undefined. (At least three implementations have been known to support this change already, so the degree of change involved should not be great.)

The '%' operator is the mathematical remainder operator when **scale** is zero. The behavior of this operator for other values of **scale** is from historical implementations of *bc*, and has been maintained for the sake of historical applications despite its non-intuitive nature.

Historical implementations permit setting **ibase** and **obase** to a broader range of values. This includes values less than 2, which were not seen as sufficiently useful to standardize. These implementations do not interpret input properly for values of **ibase** that are greater than 16. This is because numeric constants are recognized syntactically, rather than lexically, as described in this volume of IEEE Std. 1003.1-200x. They are built from lexical tokens of single hexadecimal digits and periods. Since <blank>s between tokens are not visible at the syntactic level, it is not possible to recognize the multi-digit ''digits'' used in the higher bases properly. The ability to recognize input in these bases was not considered useful enough to require modifying these implementations. Note that the recognition of numeric constants at the syntactic level is not a problem with conformance to this volume of IEEE Std. 1003.1-200x, as it does not impact the behavior of portable applications (and correct *bc* programs). Historical implementations also accept input with all of the digits '0'–'9' and 'A'–'F' regardless of the value of **ibase**; since digits with value greater than or equal to **ibase** are not really appropriate, the behavior when they appear is undefined, except for the common case of:

```
ibase=8;
    /* Process in octal base. */
...
ibase=A
    /* Restore decimal base. */
```

In some historical implementations, if the expression to be written is an uninitialized array element, a leading <space> character and/or up to four leading 0 characters may be output before the character zero. This behavior is considered a bug; it is unlikely that any currently portable application relies on:

```
echo 'b[3]' | bc
```

returning 00000 rather than 0.

Exact calculation of the number of fractional digits to output for a given value in a base other than 10 can be computationally expensive. Historical implementations use a faster approximation, and this is permitted. Note that the requirements apply only to values of **obase** that this volume of IEEE Std. 1003.1-200x requires implementations to support (in particular, not to 1, 0, or negative bases, if an implementation supports them as an extension).

Historical implementations of *bc* did not allow array parameters to be passed as the last parameter to a function. New implementations are encouraged to remove this restriction even though it is not required by the grammar.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

Updated to align with the IEEE P1003.2b draft standard, which included resolution of several interpretations of the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

8036 **NAME**

8037 bg — run jobs in the background

8038 **SYNOPSIS**

8039 UP
```
bg [job_id ...]
```
8040

8041 **DESCRIPTION**

8042 If job control is enabled (see the description of *set* −**m**), the *bg* utility shall resume suspended jobs
8043 from the current environment (see Section 2.13 (on page 2273)) by running them as background
8044 jobs. If the job specified by *job_id* is already a running background job, the *bg* utility shall have no
8045 effect and shall exit successfully.

8046 Using *bg* to place a job into the background shall cause its process ID to become ‘‘known in the
8047 current shell execution environment’’, as if it had been started as an asynchronous list; see
8048 Section 2.9.3.1 (on page 2259).

8049 **OPTIONS**

8050 None.

8051 **OPERANDS**

8052 The following operand shall be supported:

8053 *job_id* Specify the job to be resumed as a background job. If no *job_id* operand is given,
8054 the most recently suspended job shall be used. The format of *job_id* is described in |
8055 the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.205, Job Control |
8056 Job ID. |

8057 **STDIN**

8058 Not used.

8059 **INPUT FILES**

8060 None.

8061 **ENVIRONMENT VARIABLES**

8062 The following environment variables shall affect the execution of *bg*:

8063 *LANG* Provide a default value for the internationalization variables that are unset or null.
8064 If *LANG* is unset or null, the corresponding value from the implementation- |
8065 defined default locale shall be used. If any of the internationalization variables |
8066 contains an invalid setting, the utility shall behave as if none of the variables had
8067 been defined.

8068 *LC_ALL* If set to a non-empty string value, override the values of all the other
8069 internationalization variables.

8070 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
8071 characters (for example, single-byte as opposed to multi-byte characters in
8072 arguments).

8073 *LC_MESSAGES*
8074 Determine the locale that should be used to affect the format and contents of
8075 diagnostic messages written to standard error.

8076 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

8077 **ASYNCHRONOUS EVENTS**
8078 Default.

8079 **STDOUT**
8080 The output of *bg* shall consist of a line in the format:

8081 `"[%d] %s\n", <job-number>, <command>`

8082 where the fields are as follows:

8083 <*job-number*> A number that can be used to identify the job to the *wait*, *fg*, and *kill* utilities. Using
8084 these utilities, the job can be identified by prefixing the job number with '%'.

8085 <*command*> The associated command that was given to the shell.

8086 **STDERR**
8087 Used only for diagnostic messages.

8088 **OUTPUT FILES**
8089 None.

8090 **EXTENDED DESCRIPTION**
8091 None.

8092 **EXIT STATUS**
8093 The following exit values shall be returned:

8094 0 Successful completion.

8095 >0 An error occurred.

8096 **CONSEQUENCES OF ERRORS**
8097 If job control is disabled, the *bg* utility shall exit with an error and no job shall be placed in the
8098 background.

8099 **APPLICATION USAGE**
8100 A job is generally suspended by typing the SUSP character (<control>-Z on most systems); see
8101 the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 11, General Terminal Interface. At
8102 that point, *bg* can put the job into the background. This is most effective when the job is
8103 expecting no terminal input and its output has been redirected to non-terminal files. A
8104 background job can be forced to stop when it has terminal output by issuing the command:

8105 `stty tostop`

8106 A background job can be stopped with the command:

8107 `kill –s stop` *`job ID`*

8108 The *bg* utility does not work as expected when it is operating in its own utility execution
8109 environment because that environment has no suspended jobs. In the following examples:

8110 `... | xargs bg`
8111 `(bg)`

8112 each *bg* operates in a different environment and does not share its parent shell's understanding
8113 of jobs. For this reason, *bg* is generally implemented as a shell regular built-in.

8114 **EXAMPLES**
8115 None.

8116 **RATIONALE**

8117 The extensions to the shell specified in this volume of IEEE Std. 1003.1-200x have mostly been
8118 based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs*
8119 are also based on the KornShell. The standard developers examined the characteristics of the C
8120 shell versions of these utilities and found that differences exist. Despite widespread use of the C
8121 shell, the KornShell versions were selected for this volume of IEEE Std. 1003.1-200x to maintain a
8122 degree of uniformity with the rest of the KornShell features selected (such as the very popular
8123 command line editing features).

8124 The *bg* utility is expected to wrap its output if the output exceeds the number of display
8125 columns.

8126 **FUTURE DIRECTIONS**

8127 None.

8128 **SEE ALSO**

8129 *fg*, *kill*, *jobs*, *wait*

8130 **CHANGE HISTORY**

8131 First released in Issue 4.

8132 **Issue 6**

8133 This utility is now marked as part of the User Portability Utilities option.

8134 The JC margin marker on the SYNOPSIS is removed since support for Job Control is mandatory |
8135 in this issue. This is a FIPS requirement.

NAME

c99 — compile standard C programs

SYNOPSIS

CD

```
c99 [–c][–D name[=value]]...[–E][–g][–I directory] ... [–L directory]
    ... [–o outfile][–O][–s][–U name]... operand ...
```

DESCRIPTION

The *c99* utility is an interface to the standard C compilation system; it shall accept source code conforming to the ISO C standard. The system conceptually consists of a compiler and link editor. The files referenced by *operand*s shall be compiled and linked to produce an executable file. (It is unspecified whether the linking occurs entirely within the operation of *c99*; some systems may produce objects that are not fully resolved until the file is executed.)

If the **–c** option is specified, for all path name operands of the form *file***.c**, the files:

`$(basename` *pathname* `.c).o`

shall be created as the result of successful compilation. If the **–c** option is not specified, it is unspecified whether such **.o** files are created or deleted for the *file***.c** operands.

If there are no options that prevent link editing (such as **–c** or **–E**), and all operands compile and link without error, the resulting executable file shall be written according to the **–o** *outfile* option (if present) or to the file **a.out**.

The executable file shall be created as specified in Section 1.7.1.4 (on page 2209), except that the file permission bits shall be set to:

S_IRWXO | S_IRWXG | S_IRWXU

and the bits specified by the *umask* of the process shall be cleared.

OPTIONS

The *c99* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that:

- The **–l** *library* operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.
- The order of specifying the **–I** and **–L** options is significant.
- Portable applications shall specify each option separately; that is, grouping option letters (for example, **–cO**) need not be recognized by all implementations.

The following options shall be supported:

–c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.

–g Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.

–s Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the *exec* family defined in the System Interfaces volume of IEEE Std. 1003.1-200x, has been removed (stripped). If both **–g** and **–s** options are present, the action taken is unspecified.

–o *outfile* Use the path name *outfile*, instead of the default **a.out**, for the executable file produced. If the **–o** option is present with **–c** or **–E**, the result is unspecified.

–D *name***[=***value***]**
Define *name* as if by a C-language **#define** directive. If no =*value* is given, a value of 1 shall be used. The **–D** option has lower precedence than the **–U** option. That is, if *name* is used in both a **–U** and a **–D** option, *name* shall be undefined regardless of the order of the options. Additional implementation-defined *name*s may be provided by the compiler. Implementations shall support at least 2 048 bytes of **–D** definitions and 256 *names*.

–E Copy C-language source files to standard output, expanding all preprocessor directives; no compilation shall be performed. If any operand is not a text file, the effects are unspecified.

–I *directory* Change the algorithm for searching for headers whose names are not absolute path names to look in the directory named by the *directory* path name before looking in the usual places. Thus, headers whose names are enclosed in double-quotes (" ") shall be searched for first in the directory of the file with the **#include** line, then in directories named in **–I** options, and last in the usual places. For headers whose names are enclosed in angle brackets ("<>"), the header shall be searched for only in directories named in **–I** options and then in the usual places. Directories named in **–I** options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single *c99* command invocation.

–L *directory* Change the algorithm of searching for the libraries named in the **–l** objects to look in the directory named by the *directory* path name before looking in the usual places. Directories named in **–L** options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single *c99* command invocation. If a directory specified by a **–L** option contains files named **libc.a**, **libm.a**, **libl.a**, or **liby.a**, the results are unspecified.

–O Optimize. The nature of the optimization is unspecified.

–U *name* Remove any initial definition of *name*.

Multiple instances of the **–D**, **–I**, **–U**, and **–L** options can be specified.

OPERANDS

An *operand* is either in the form of a path name or the form **–l** *library*. The application shall ensure that at least one operand of the path name form is specified. The following operands shall be supported:

file.**c** A C-language source file to be compiled and optionally linked. The application shall ensure that the operand is of this form if the **–c** option is used.

file.**a** A library of object files typically produced by the *ar* utility, and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.a** as denoting object file libraries.

file.**o** An object file produced by *c99* **–c** and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than **.o** as denoting object files.

The processing of other files is implementation-defined.

–*l library* (The letter ell.) Search the library named:

`lib`*`library`*`.a`

A library shall be searched when its name is encountered, so the placement of a **–l** operand is significant. Several standard libraries can be specified in this manner, as

described in the EXTENDED DESCRIPTION section. Implementations may recognize implementation-defined suffixes other than **.a** as denoting libraries.

STDIN

Not used.

INPUT FILES

The input file shall be one of the following: a text file containing a C-language source program, an object file in the format produced by *c99* **–c**, or a library of object files, in the format produced by archiving zero or more object files, using *ar*. Implementations may supply additional utilities that produce files in these formats. Additional input file formats are implementation-defined.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *c99*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Provide a path name that should override the default directory for temporary files, if any. XSI On XSI-conforming systems, provide a path name that shall override the default directory for temporary files, if any.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If more than one *file* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

`"%s:\n", <`*`file`*`>`

may be written. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard output if they are written to the standard error, as described in the STDERR section.

If the **–E** option is specified, the standard output shall be a text file that represents the results of the preprocessing stage of the language; it may contain extra information appropriate for subsequent compilation passes.

STDERR

Used only for diagnostic messages. If more than one *file* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

8267 `"%s:\n", <file>`

8268 may be written to allow identification of the diagnostic and warning messages with the
8269 appropriate input file. These messages, if written, shall precede the processing of each input file;
8270 they shall not be written to the standard error if they are written to the standard output, as
8271 described in the STDOUT section.

8272 This utility may produce warning messages about certain conditions that do not warrant
8273 returning an error (non-zero) exit value.

8274 **OUTPUT FILES**

8275 Object files or executable files or both are produced in unspecified formats.

8276 **EXTENDED DESCRIPTION**

8277 **Standard Libraries**

8278 The *c99* utility shall recognize the following **–l** operands for standard libraries:

8279 **–l c** This operand shall make visible all library functions referenced in the System
8280 Interfaces volume of IEEE Std. 1003.1-200x, with the possible exception of those
8281 functions listed as residing in **<aio.h>**, **<arpa/inet.h>**, **<math.h>**, **<mqueue.h>**,
8282 **<netdb.h>**, **<netinet/in.h>**, **<pthread.h>**, **<sched.h>**, **<semaphore.h>**,
8283 **<sys/socket.h>**, *pthread_atfork*( ) in **<unistd.h>**, and those functions marked as an
8284 RT extension in **<sys/mman.h>** and **<time.h>**. This operand shall not be required
8285 to be present to cause a search of this library.

8286 **–l l** This operand shall make visible all functions required by the C-language output of
8287 *lex* that are not made available through the **–l c** operand.

8288 **–l pthread** This operand shall make visible all functions referenced in **<pthread.h>** and
8289 *pthread_atfork*( ) referenced in **<unistd.h>**. An implementation may search this
8290 library in the absence of this operand.

8291 **–l m** This operand shall make visible all functions referenced in **<math.h>**. An
8292 implementation may search this library in the absence of this operand.

8293 **–l rt** This operand shall make visible all functions referenced in **<aio.h>**, **<mqueue.h>**,
8294 **<sched.h>**, and **<semaphore.h>**, and those functions marked as an RT extension in
8295 **<sys/mman.h>** and **<time.h>**. An implementation may search this library in the
8296 absence of this operand.

8297 **–l xnet** This operand makes visible all functions referenced in **<arpa/inet.h>**, **<netdb.h>**,
8298 **<netinet/in.h>**, and **<sys/socket.h>**. An implementation may search this library in
8299 the absence of this operand.

8300 **–l y** This operand shall make visible all functions required by the C-language output of
8301 *yacc* that are not made available through the **–l c** operand.

8302 In the absence of options that inhibit invocation of the link editor, such as **–c** or **–E**, the *c99* utility
8303 shall cause the equivalent of a **–l c** operand to be passed to the link editor as the last **–l** operand,
8304 causing it to be searched after all other object files and libraries are loaded.

8305 It is unspecified whether the libraries **libc.a**, **libm.a**, **librt.a**, **libpthread.a**, **libl.a**, **liby.a**, or **libxnet**
8306 exist as regular files. The implementation may accept as **–l** operands names of objects that do
8307 not exist as regular files.

External Symbols

The C compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; the action taken upon encountering symbols exceeding the implementation-defined maximum symbol length is unspecified.

The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4095 external symbols in total. A diagnostic message shall be written to the standard output if the implementation-defined limit is exceeded; other actions are unspecified.

Programming Environments

All implementations shall support one of the following programming environments as a default. Implementations may support more than one of the following programming environments. Applications can use *sysconf*( ) or *getconf* to determine which programming environments are supported.

Table 4-4 Programming Environments: Type Sizes

Programming Environment *getconf* **Name**	**Bits in int**	**Bits in long**	**Bits in pointer**	**Bits in off_t**
_POSIX_V6_ILP32_OFF32	32	32	32	32
_POSIX_V6_ILP32_OFFBIG	32	32	32	≥64
_POSIX_V6_LP64_OFF64	32	64	64	64
_POSIX_V6_LPBIG_OFFBIG	≥32	≥64	≥64	≥64

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

The names of the macros above may be changed. This has been added to the issues list.

Implementations provide configuration strings for C compiler flags, linker/loader flags, and libraries for each supported environment. When an application needs to use a specific programming environment rather than the implementation default programming environment while compiling, the application shall first verify that the implementation supports the desired environment. If the desired programming environment is supported, the application shall then invoke *c99* with the appropriate C compiler flags as the first options for the compile, the appropriate linker/loader flags after any other options but before any operands, and the appropriate libraries at the end of the operands.

Portable applications shall not attempt to link together object files compiled for different programming models. Applications shall also be aware that binary data placed in shared memory or in files might not be recognized by applications built for other programming models.

Table 4-5 Programming Environments: c99 and cc Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **and** *cc* **Arguments** *getconf* **Name**
_POSIX_V6_ILP32_OFF32	C Compiler Flags	POSIX_V6_ILP32_OFF32_CFLAGS
	Linker / Loader Flags	POSIX_V6_ILP32_OFF32_LDFLAGS
	Libraries	POSIX_V6_ILP32_OFF32_LIBS
_POSIX_V6_ILP32_OFFBIG	C Compiler Flags	POSIX_V6_ILP32_OFFBIG_CFLAGS
	Linker / Loader Flags	POSIX_V6_ILP32_OFFBIG_LDFLAGS
	Libraries	POSIX_V6_ILP32_OFFBIG_LIBS
_POSIX_V6_LP64_OFF64	C Compiler Flags	POSIX_V6_LP64_OFF64_CFLAGS
	Linker / Loader Flags	POSIX_V6_LP64_OFF64_LDFLAGS
	Libraries	POSIX_V6_LP64_OFF64_LIBS
_POSIX_V6_LPBIG_OFFBIG	C Compiler Flags	POSIX_V6_LPBIG_OFFBIG_CFLAGS
	Linker / Loader Flags	POSIX_V6_LPBIG_OFFBIG_LDFLAGS
	Libraries	POSIX_V6_LPBIG_OFFBIG_LIBS

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

The names of the macros above may be changed. This has been added to the issues list.

EXIT STATUS

The following exit values shall be returned:

0 Successful compilation or link edit.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When *c99* encounters a compilation error that causes an object file not to be created, it shall write a diagnostic to standard error and continue to compile other source code operands, but it shall not perform the link phase and return a non-zero exit status. If the link edit is unsuccessful, a diagnostic message shall be written to standard error and *c99* exits with a non-zero status. A portable application shall rely on the exit status of *c99*, rather than on the existence or mode of the executable file.

APPLICATION USAGE

Since the *c99* utility usually creates files in the current directory during the compilation process, it is typically necessary to run the *c99* utility in a directory in which a file can be created.

On systems providing POSIX Conformance (see the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 2, Conformance), *c99* is required only with the the C-Language Development option; XSI-conformant systems always provide *c99*.

Some historical implementations have created **.o** files when **–c** is not specified and more than one source file is given. Since this area is left unspecified, the application cannot rely on **.o** files being created, but it also must be prepared for any related **.o** files that already exist being deleted at the completion of the link edit.

Some historical implementations have permitted **–L** options to be interspersed with **–l** operands on the command line. For an application to compile consistently on systems that do not behave like this, it is necessary for a portable application to supply all **–L** options before any of the **–l** options.

There is the possible implication that if a user supplies versions of the standard library functions (before they would be encountered by an implicit **–l c** or explicit **–l m**), that those versions would be used in place of the standard versions. There are various reasons this might not be true (functions defined as macros, manipulations for clean name space, and so on), so the existence of files named in the same manner as the standard libraries within the **–L** directories is explicitly stated to produce unspecified behavior.

All of the functions specified in the System Interfaces volume of IEEE Std. 1003.1-200x may be made visible by implementations when the Standard C Library is searched. Portable applications must explicitly request searching the other standard libraries when functions made visible by those libraries are used.

EXAMPLES

1. The following usage example compiles **foo.c** and creates the executable file **foo**:

   ```
   c99 –o foo foo.c
   ```

   The following usage example compiles **foo.c** and creates the object file **foo.o**:

   ```
   c99 –c foo.c
   ```

   The following usage example compiles **foo.c** and creates the executable file **a.out**:

   ```
   c99 foo.c
   ```

   The following usage example compiles **foo.c**, links it with **bar.o**, and creates the executable file **a.out**. It also creates and leaves **foo.o**:

   ```
   c99 foo.c bar.o
   ```

2. The following example shows how an application using threads interfaces can test for support of and use a programming environment supporting 32-bit **int**, **long**, and **pointer** types and an **off_t** type using at least 64 bits:

   ```
   if [ $(getconf _POSIX_V6_ILP32_OFFBIG) != "–1" ]
   then
       c99 $(getconf POSIX_V6_ILP32_OFFBIG_CFLAGS) –D_XOPEN_SOURCE=600 \
           $(getconf POSIX_V6_ILP32_OFFBIG_LDFLAGS) foo.c –o foo \
           $(getconf POSIX_V6_ILP32_OFFBIG_LIBS) –l pthread
   else
       echo ILP32_OFFBIG programming environment not supported
       exit 1
   fi
   ```

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

The names of the macros above may be changed. This has been added to the issues list.

3. The following examples clarify the use and interactions of **–L** options and **–l** operands.

   Consider the case in which module **a.c** calls function *f*( ) in library **libQ.a**, and module **b.c** calls function *g*( ) in library **libp.a**. Assume that both libraries reside in **/a/b/c**. The command line to compile and link in the desired way is:

   ```
   c99 –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this case the **–l Q** operand need only precede the first **–l p** operand, since both **libQ.a** and **libp.a** reside in the same directory.

   Multiple **–L** operands can be used when library name collisions occur. Building on the previous example, suppose that the user wants to use a new **libp.a**, in **/a/a/a**, but still wants *f*( ) from **/a/b/c/libQ.a**:

   ```
   c99 –L /a/a/a –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this example, the linker searches the **–L** options in the order specified, and finds **/a/a/a/libp.a** before **/a/b/c/libp.a** when resolving references for **b.c**. The order of the **–l** operands is still important, however.

RATIONALE

The *c99* utility is based on the *c89* utility originally introduced in the ISO POSIX-2: 1993 standard. |

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Included for alignment with the ISO / IEC 9899: 1999 standard. |

NAME

cal — print a calendar

SYNOPSIS

XSI
```
cal [[month] year ]
```

DESCRIPTION

The *cal* utility shall write a calendar to standard output using the Julian calendar for dates from January 1, 1 through September 2, 1752 and the Gregorian calendar for dates from September 14, 1752 through December 31, 9999 as though the Gregorian calendar had been adopted on September 14, 1752.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

month Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default shall be the current month.

year Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default shall be the current year.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cal*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

LC_TIME Determine the format and contents of the calendar.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used to calculate the value of the current month.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to display the calendar, in an unspecified format.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that:

```
cal 83
```

refers to A.D. 83, not 1983.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

A future revision of IEEE Std. 1003.1-200x may support locale-specific recognition of the date of adoption of the Gregorian calendar.

SEE ALSO

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Internationalized environment variable support mandated.

Issue 6

The DESCRIPTION is updated to allow for traditional behavior for years before the adoption of the Gregorian calendar.

8521 **NAME**

8522 cat — concatenate and print files

8523 **SYNOPSIS**

8524 `cat [`–u`][`*file* `...]`

8525 **DESCRIPTION**

8526 The *cat* utility reads files in sequence and writes their contents to the standard output in the
8527 same sequence.

8528 **OPTIONS**

8529 The *cat* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
8530 12.2, Utility Syntax Guidelines.

8531 The following option shall be supported:

8532 **–u** Write bytes from the input file to the standard output without delay as each is
8533 read.

8534 **OPERANDS**

8535 The following operand shall be supported:

8536 *file* A path name of an input file. If no *file* operands are specified, the standard input is
8537 used. If a *file* is `'–'`, the *cat* utility shall read from the standard input at that point
8538 in the sequence. The *cat* utility shall not close and reopen standard input when it is
8539 referenced in this way, but shall accept multiple occurrences of `'–'` as a *file*
8540 operand.

8541 **STDIN**

8542 The standard input is used only if no *file* operands are specified, or if a *file* operand is `'–'`. See
8543 the INPUT FILES section.

8544 **INPUT FILES**

8545 The input files can be any file type.

8546 **ENVIRONMENT VARIABLES**

8547 The following environment variables shall affect the execution of *cat*:

8548 *LANG* Provide a default value for the internationalization variables that are unset or null.
8549 If *LANG* is unset or null, the corresponding value from the implementation-
8550 defined default locale shall be used. If any of the internationalization variables
8551 contains an invalid setting, the utility shall behave as if none of the variables had
8552 been defined.

8553 *LC_ALL* If set to a non-empty string value, override the values of all the other
8554 internationalization variables.

8555 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
8556 characters (for example, single-byte as opposed to multi-byte characters in
8557 arguments).

8558 *LC_MESSAGES*

8559 Determine the locale that should be used to affect the format and contents of
8560 diagnostic messages written to standard error.

8561 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

8562 **ASYNCHRONOUS EVENTS**
8563 Default.

8564 **STDOUT**
8565 The standard output shall contain the sequence of bytes read from the input files. Nothing else
8566 shall be written to the standard output.

8567 **STDERR**
8568 Used only for diagnostic messages.

8569 **OUTPUT FILES**
8570 None.

8571 **EXTENDED DESCRIPTION**
8572 None.

8573 **EXIT STATUS**
8574 The following exit values shall be returned:

8575 0 All input files were output successfully.

8576 >0 An error occurred.

8577 **CONSEQUENCES OF ERRORS**
8578 Default.

8579 **APPLICATION USAGE**
8580 The **–u** option has value in prototyping non-blocking reads from FIFOs. The intent is to support
8581 the following sequence:

```
8582 mkfifo foo
8583 cat –u foo > /dev/tty13 &
8584 cat –u > foo
```

8585 It is unspecified whether standard output is or is not buffered in the default case. This is
8586 sometimes of interest when standard output is associated with a terminal, since buffering may
8587 delay the output. The presence of the **–u** option guarantees that unbuffered I/O is available. It is |
8588 implementation-defined whether the *cat* utility buffers output if the **–u** option is not specified. |
8589 Traditionally, the **–u** option is implemented using the equivalent of the *setvbuf*( ) function
8590 defined in the System Interfaces volume of IEEE Std. 1003.1-200x.

8591 **EXAMPLES**
8592 The following command:

```
8593 cat myfile
```

8594 writes the contents of the file **myfile** to standard output.

8595 The following command:

```
8596 cat doc1 doc2 > doc.all
```

8597 concatenates the files **doc1** and **doc2** and writes the result to **doc.all**.

8598 Because of the shell language mechanism used to perform output redirection, a command such
8599 as this:

```
8600 cat doc doc.end > doc
```

8601 causes the original data in **doc** to be lost.

8602 The command:

```
cat start – middle – end > file
```

when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of *cat*. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start – middle /dev/null end > file
```

because the entire contents of the file would be consumed by *cat* the first time '–' was used as a *file* operand and an end-of-file condition would be detected immediately when '–' was referenced the second time.

RATIONALE

Historical versions of the *cat* utility include the options –**e**, –**t**, and –**v**, which permit the ends of lines, <tab>s, and invisible characters, respectively, to be rendered visible in the output. The standard developers omitted these options because they provide too fine a degree of control over what is made visible, and similar output can be obtained using a command such as:

```
sed –n –e 's/$/$/' –e l pathname
```

The –**s** option was omitted because it corresponds to different functions in BSD and System V-based systems. The BSD –**s** option to squeeze blank lines can be accomplished by the shell script shown in following example:

```
sed –n '
# Write non-empty lines.
/./   {
      p
      d
      }
# Write a single empty line, then look for more empty lines.
/^$/  p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/  {
      N
      s///
      b Empty
      }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
      p
'
```

The System V –**s** option to silence error messages can be accomplished by redirecting the standard error. Note that the BSD documentation for *cat* uses the term ‘‘blank line’’ to mean the same as the POSIX ‘‘empty line’’: a line consisting only of a <newline>.

The BSD –**n** option was omitted because similar functionality can be obtained from the –**n** option of the *pr* utility.

FUTURE DIRECTIONS

None.

8649 **CHANGE HISTORY**

8650 First released in Issue 2.

8651 **Issue 4**

8652 Aligned with the ISO / IEC 9945-2: 1993 standard.

8653 **NAME**

8654 cd — change the working directory

8655 **SYNOPSIS**

8656 `cd [-L] [-P] [`*directory*`]`

8657 `cd -`

8658 **DESCRIPTION**

8659 The *cd* utility shall change the working directory of the current shell execution environment (see
8660 Section 2.13 (on page 2273)) by executing the following steps in sequence. (In the following
8661 steps, the symbol **curpath** represents an intermediate value used to simplify the description of
8662 the algorithm used by *cd*. There is no requirement that **curpath** be made visible to the
8663 application.)

8664 1. If no *directory* operand is given and the *HOME* environment variable is empty or
8665 undefined, the default behavior is implementation-defined and no further steps shall be
8666 taken.

8667 2. If no *directory* operand is given and the *HOME* environment variable is set to a non-empty
8668 value, the *cd* utility shall behave as if the directory named in the *HOME* environment
8669 variable was specified as the *directory* operand.

8670 3. If the *directory* operand begins with a slash character, set **curpath** to the operand and
8671 proceed to step 7.

8672 4. If the first component of the *directory* operand is dot or dot-dot, proceed to step 6.

8673 5. Starting with the first path name in the colon-separated path names of *CDPATH* (see the
8674 ENVIRONMENT VARIABLES section) if the path name is non-null, test if the
8675 concatenation of that path name, a slash character, and the *directory* operand names a
8676 directory. If the path name is null, test if the concatenation of dot, a slash character, and the
8677 operand names a directory. In either case, if the resulting string names an existing
8678 directory, set **curpath** to that string and proceed to step 7. Otherwise, repeat this step with
8679 the next path name in *CDPATH* until all path names have been tested.

8680 6. Set **curpath** to the string formed by the concatenation of the value of *PWD* a slash
8681 character, and the operand.

8682 7. If the **–P** option is in effect, the *cd* utility shall perform actions equivalent to the *chdir*( )
8683 function, called with **curpath** as the *path* argument. If these actions succeed, the *PWD*
8684 environment variable shall be set to an absolute path name for the current working
8685 directory and shall not contain file name components that, in the context of path name
8686 resolution, refer to a file of type symbolic link. If there is insufficient permission on the new
8687 directory, or on any parent of that directory, to determine the current working directory,
8688 the value of the *PWD* environment variable is unspecified. If the actions equivalent to
8689 *chdir*( ) fail for any reason, the *cd* utility shall display an appropriate error message and not
8690 alter the *PWD* environment variable. Whether the actions equivalent to *chdir*( ) succeed or
8691 fail, no further steps shall be taken.

8692 8. The **curpath** value shall then be converted to canonical form as follows, considering each
8693 component from beginning to end, in sequence:

8694 a. Dot components and any slashes that separate them from the next component shall
8695 be deleted.

8696 b. For each dot-dot component, if there is a preceding component and it is neither root
8697 nor dot-dot, the preceding component, all slashes separating the preceding
8698 component from dot-dot, dot-dot, and all slashes separating dot-dot from the

following component shall be deleted.

c. An implementation may further simplify **curpath** by removing any trailing slash characters that are not also leading slashes, replacing multiple non-leading consecutive slashes with a single slash, and replacing three or or more leading slashes with a single slash. If, as a result of this canonicalization, the **curpath** variable is null, no further steps shall be taken.

9. The *cd* utility shall then perform actions equivalent to the *chdir*( ) function called with **curpath** as the *path* argument. If these actions failed for any reason, the *cd* utility shall display an appropriate error message and no further steps shall be taken. The *PWD* environment variable shall be set to **curpath**.

If, during the execution of the above steps, the *PWD* environment variable is changed, the *OLDPWD* environment variable shall also be changed to the value of the old working directory (that is the current working directory immediately prior to the call to *cd*).

OPTIONS

The *cd* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–L Handle the operand dot-dot logically; symbolic link components shall not be resolved before dot-dot components are processed (see steps 5. and 6. in the DESCRIPTION).

–P Handle the operand dot-dot physically; symbolic link components shall be resolved before dot-dot components are processed (see step 4. in the DESCRIPTION).

If both **–L** and **–P** options are specified, the last of these options shall be used and all others ignored. If neither **–L** nor **–P** is specified, the operand shall be handled dot-dot logically; see the DESCRIPTION.

OPERANDS

The following operands shall be supported:

directory An absolute or relative path name of the directory that shall become the new working directory. The interpretation of a relative path name by *cd* depends on the **–L** option and the *CDPATH* and *PWD* environment variables. If *directory* is an empty string, the results are unspecified.

– When a hyphen is used as the operand, this is equivalent to the command:

```
cd "$OLDPWD" && pwd
```

which changes to the previous working directory and then writes its name.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cd*:

CDPATH A colon-separated list of path names that refer to directories. The *cd* utility shall use this list in its attempt to change the directory, as described in the DESCRIPTION. An empty string in place of a directory path name represents the

current directory. If *CDPATH* is not set, it shall be treated as if it were an empty string.

HOME The name of the directory, used when no *directory* operand is specified.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

OLDPWD A path name of the previous working directory, used by *cd* –.

PWD This variable shall be set as specified in the DESCRIPTION. If an application sets or unsets the value of *PWD*, the behavior of *cd* is unspecified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If a non-empty directory name from *CDPATH* is used, or if *cd* – is used, an absolute path name of the new working directory shall be written to the standard output as follows:

`"%s\n", <new directory>`

Otherwise, there shall be no output.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The directory was successfully changed.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The working directory shall remain unchanged.

8782 **APPLICATION USAGE**

8783 Since *cd* affects the current shell execution environment, it is always provided as a shell regular
8784 built-in. If it is called in a subshell or separate utility execution environment, such as one of the
8785 following:

```
8786 (cd /tmp)
8787 nohup cd
8788 find . –exec cd {} \;
```

8789 it does not affect the working directory of the caller's environment.

8790 The user must have execute (search) permission in *directory* in order to change to it.

8791 **EXAMPLES**

8792 None.

8793 **RATIONALE**

8794 The use of the *CDPATH* was introduced in the System V shell. Its use is analogous to the use of
8795 the *PATH* variable in the shell. The BSD C shell used a shell parameter *cdpath* for this purpose.

8796 A common extension when *HOME* is undefined is to get the login directory from the user
8797 database for the invoking user. This does not occur on System V implementations.

8798 Some historical shells, such as the KornShell, took special actions when the directory name
8799 contained a dot-dot component, selecting the logical parent of the directory, rather than the
8800 actual parent directory; that is, it moved up one level toward the `'/'` in the path name,
8801 remembering what the user typed, rather than performing the equivalent of:

```
8802 chdir("..");
```

8803 In such a shell, the following commands would not necessarily produce equivalent output for all
8804 directories:

```
8805 cd .. && ls      ls ..
```

8806 This behavior is not permitted by default because it is not consistent with the definition of dot-
8807 dot in most historical practice; that is, while this behavior has been optionally available in the
8808 KornShell, other shells have historically not supported this functionality. The logical path name
8809 is stored in the *PWD* environment variable when the *cd* utility completes and this value is used
8810 to construct the next directory name if *cd* is invoked with the **–L** option.

8811 **FUTURE DIRECTIONS**

8812 None.

8813 **SEE ALSO**

8814 *pwd*, the System Interfaces volume of IEEE Std. 1003.1-200x, *chdir*( )

8815 **CHANGE HISTORY**

8816 First released in Issue 2.

8817 **Issue 4**

8818 Aligned with the ISO / IEC 9945-2: 1993 standard.

8819 Extensions added for *cd –*, *PWD*, and *OLDPWD*.

8820 **Issue 6**

8821 The following new requirements on POSIX implementations derive from alignment with the
8822 Single UNIX Specification:

8823 • The *cd –*, *PWD*, and *OLDPWD* are added.

The **–L** and **–P** options are added to align with the IEEE P1003.2b draft standard. This also includes the introduction of a new description to include the effect of these options.

NAME

cflow — generate a C-language flowgraph (**DEVELOPMENT**)

SYNOPSIS

XSI

```
cflow [–r][–d num][–D name[=def]] ... [–i incl][–I dir] ...
    [–U dir] ... file ...
```

DESCRIPTION

The *cflow* utility shall analyse a collection of object files or assembler, C-language, *lex* or *yacc* source files, and attempt to build a graph, written to standard output, charting the external references.

OPTIONS

The *cflow* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the **–D**, **–I**, and **–U** options (which are identical to their interpretation by *c99*) is significant.

The following options shall be supported:

–d *num* Indicate the depth at which the flowgraph is cut off. The application shall ensure that the argument *num* is a decimal integer. By default this is a very large number (typically greater than 32 000). Attempts to set the cut-off depth to a non-positive integer are ignored.

–i *incl* Increase the number of included symbols. The *incl* option-argument is one of the following characters:

x Include external and static data symbols. The default shall be to include only functions in the flowgraph.

_ (Underscore) Include names that begin with an underscore. The default shall be to exclude these functions (and data if **–i x** is used).

–r Reverse the caller:callee relationship, producing an inverted listing showing the callers of each function. The listing is also sorted in lexicographical order by callee.

OPERANDS

The following operand is supported:

file The path name of a file for which a graph is to be generated. Files suffixed in **.l**, **.y**, **.c**, and **.i** shall be processed by *lex* and *yacc* and preprocessed by the *c99* preprocessor phase (bypassed for **.i** files) as appropriate, and then run through the first pass of *lint*. Files suffixed with **.s** shall be assembled and information shall be extracted (as in **.o** files) from the symbol table.

STDIN

Not used.

INPUT FILES

The input files shall be object files or assembler, C-language, *lex* or *yacc* source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cflow*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output when the **–r** option is used.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The flowgraph written to standard output shall be formatted as follows:

`"%d %s:%s\n", <reference number>, <global>, <definition>`

Each line of output begins with a reference (that is, line) number, followed by indentation of at least one column position per level. This is followed by the name of the global, a colon, and its definition. Normally globals are only functions not defined as an external or beginning with an underscore; see the OPTIONS section for the **–i** inclusion option. For information extracted from C-language source, the definition consists of an abstract type declaration (for example, **char***) and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the file name and location counter under which the symbol appeared (for example, *text*).

Once a definition of a name has been written, subsequent references to that name contain only the reference number of the line where the definition can be found. For undefined references, only `"<>"` shall be written.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE

Files produced by *lex* and *yacc* cause the reordering of line number declarations, and this can confuse *cflow*. To obtain proper results, the input of *yacc* or *lex* must be directed to *cflow*.

EXAMPLES

Given the following in **file.c**:

```
int i;
main()
{
    f();
    g();
    f();
}
f()
{
    i = h();
}
```

The command:

```
cflow –i x file.c
```

produces the output:

```
1 main: int(), <file.c 2>
2    f: int(), <file.c 8>
3        h: <>
4        i: int, <file.c 1>
5    g: <>
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Internationalized environment variable support mandated.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

chgrp — change the file group ownership

SYNOPSIS

```
chgrp –hR group file ...
chgrp –R [–H | –L | –P ] group file ...
```

DESCRIPTION

The *chgrp* utility shall set the group ID of the file named by each *file* operand to the group ID specified by the *group* operand.

For each *file* operand, it shall perform actions equivalent to the *chown*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, called with the following arguments:

- The *file* operand shall be used as the *path* argument.
- The user ID of the file shall be used as the *owner* argument.
- The specified group ID shall be used as the *group* argument.

Unless *chgrp* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chgrp* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–h If the system supports group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall attempt to set the group ID of the symbolic link instead of the file referenced by the symbolic link. If the system does not support group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall do nothing more with the current file and shall go on to any remaining files.

–H If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–L If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–P If the **–R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group ID of the symbolic link if the system supports this operation. The *chgrp* utility shall not follow the symbolic link to any other part of the file hierarchy.

–R Recursively change file group IDs. For each *file* operand that names a directory, *chgrp* shall change the group of the directory and all files in the file hierarchy below it. Unless a **–H**, **–L**, or **–P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

group A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the *file* operands. If a numeric *group* operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.

file A path name of a file whose group ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chgrp*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some systems restrict the use of *chgrp* to a user with appropriate privileges when the *group* specified is not the effective group ID or one of the supplementary group IDs of the calling process.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. The standard developers chose to mask these by specifying only 0 and >0 as exit values.

The functionality of *chgrp* is described substantially through references to *chown*( ). In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

FUTURE DIRECTIONS

None.

SEE ALSO

chmod, *chown*, the System Interfaces volume of IEEE Std. 1003.1-200x, *chown*( )

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

New options **–H**, **–L**, and **–P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ‘‘Default.’’.

NAME

chmod — change the file modes

SYNOPSIS

`chmod [–R] mode file ...`

DESCRIPTION

The *chmod* utility shall change any or all of the file mode bits of the file named by each *file* operand in the way specified by the *mode* operand.

It is implementation-defined whether and how the *chmod* utility affects any alternate or additional file access control mechanism (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 4.1, File Access Permissions) being used for the specified file.

Only a process whose effective user ID matches the user ID of the file, or a process with the appropriate privileges, shall be permitted to change the file mode bits of a file.

OPTIONS

The *chmod* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–R Recursively change file mode bits. For each *file* operand that names a directory, *chmod* shall change the file mode bits of the directory and all files in the file hierarchy below it.

OPERANDS

The following operands shall be supported:

mode Represents the change to be made to the file mode bits of each file named by one of the *file* operands; see the EXTENDED DESCRIPTION section.

file A path name of a file whose file mode bits shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chmod*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *mode* operand shall be either a *symbolic_mode* expression or a non-negative octal integer. The *symbolic_mode* form is described by the grammar later in this section.

Each **clause** shall specify an operation to be performed on the current file mode bits of each *file*. The operations shall be performed on each *file* in the order in which the **clause**s are specified.

The **who** symbols **u**, **g**, and **o** shall specify the *user*, *group*, and *other* parts of the file mode bits, respectively. A **who** consisting of the symbol **a** shall be equivalent to **ugo**.

The **perm** symbols **r**, **w**, and **x** represent the *read*, *write*, and *execute*/*search* portions of file mode bits, respectively. The **perm** symbol **s** shall represent the *set-user-ID-on-execution* (when **who** contains or implies **u**) and *set-group-ID-on-execution* (when **who** contains or implies **g**) bits.

The **perm** symbol **X** shall represent the execute/search portion of the file mode bits if the file is a directory or if the current (unmodified) file mode bits have at least one of the execute bits (S_IXUSR, S_IXGRP, or S_IXOTH) set. It shall be ignored if the file is not a directory and none of the execute bits are set in the current file mode bits.

The **permcopy** symbols **u**, **g**, and **o** shall represent the current permissions associated with the user, group, and other parts of the file mode bits, respectively. For the remainder of this section, **perm** refers to the non-terminals **perm** and **permcopy** in the grammar.

If multiple **actionlist**s are grouped with a single **wholist** in the grammar, each **actionlist** shall be applied in the order specified with that **wholist**. The *op* symbols shall represent the operation performed, as follows:

+ If **perm** is not specified, the '+' operation shall not change the file mode bits.

  If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

  Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

– If **perm** is not specified, the '–' operation shall not change the file mode bits.

  If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be cleared.

  Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be cleared.

= Clear the file mode bits specified by the **who** value, or, if no **who** value is specified, all of the file mode bits specified in this volume of IEEE Std. 1003.1-200x.

If **perm** is not specified, the '=' operation shall make no further modifications to the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

When using the symbolic mode form on a regular file, it is implementation-defined whether or not:

- Requests to set the set-user-ID-on-execution or set-group-ID-on-execution bit when all execute bits are currently clear and none are being set are ignored.
- Requests to clear all execute bits also clear the set-user-ID-on-execution and set-group-ID-on-execution bits.
- Requests to clear the set-user-ID-on-execution or set-group-ID-on-execution bits when all execute bits are currently clear are ignored. However, if the command *ls* –**l** *file* writes an *s* in the position indicating that the set-user-ID-on-execution or set-group-ID-on-execution is set, the commands *chmod* **u**–**s** *file* or *chmod* **g**–**s** *file*, respectively, shall not be ignored.

When using the symbolic mode form on other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

If the **who** symbol **o** is used in conjunction with the **perm** symbol **s** with no other **who** symbols being specified, the set-user-ID-on-execution and set-group-ID-on-execution bits shall not be modified. It shall not be an error to specify the **who** symbol **o** in conjunction with the **perm** symbol **s**.

For an octal integer *mode* operand, the file mode bits shall be set absolutely.

For each bit set in the octal number, the corresponding file permission bit shown in the following table shall be set; all other file permission bits shall be cleared. For regular files, for each bit set in the octal number corresponding to the set-user-ID-on-execution or the set-group-ID-on-execution, bits shown in the following table shall be set; if these bits are not set in the octal number, they are cleared. For other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

Octal	**Mode Bit**	**Octal**	**Mode Bit**	**Octal**	**Mode Bit**	**Octal**	**Mode Bit**
4000	S_ISUID	**0400**	S_IRUSR	**0040**	S_IRGRP	**0004**	S_IROTH
2000	S_ISGID	**0200**	S_IWUSR	**0020**	S_IWGRP	**0002**	S_IWOTH
		0100	S_IXUSR	**0010**	S_IXGRP	**0001**	S_IXOTH

When bits are set in the octal number other than those listed in the table above, the behavior is unspecified.

Grammar for chmod

The grammar and lexical conventions in this section describe the syntax for the *symbolic_mode* operand. The general conventions for this style of grammar are described in Section 1.10 (on page 2223). A valid *symbolic_mode* can be represented as the non-terminal symbol *symbolic_mode* in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

The lexical processing is based entirely on single characters. Implementations need not allow blank characters within the single argument being processed.

```
%start    symbolic_mode
%%

symbolic_mode    : section
                 | symbolic_mode ',' clause
                 ;

clause           : actionlist
                 | wholist actionlist
                 ;

wholist          : who
                 | wholist who
                 ;

who              : 'u' | 'g' | 'o' | 'a'
                 ;

actionlist       : action
                 | actionlist action
                 ;

action           : op
                 | op permlist
                 | op permcopy
                 ;

permcopy         : 'u' | 'g' | 'o'
                 ;

op               : '+' | '-' | '='
                 ;

permlist         : perm
                 | perm permlist
                 ;

perm             : 'r' | 'w' | 'x' | 'X' | 's'
                 ;
```

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Some implementations of the *chmod* utility change the mode of a directory before the files in the directory when performing a recursive (**–R** option) change; others change the directory mode after the files in the directory. If an application tries to remove read or search permission for a file hierarchy, the removal attempt fails if the directory is changed first; on the other hand, trying to re-enable permissions to a restricted hierarchy fails if directories are changed last. Users should not try to make a hierarchy inaccessible to themselves.

Some implementations of *chmod* never used the process' *umask* when changing modes; systems conformant with this volume of IEEE Std. 1003.1-200x do so when **who** is not specified. Note the difference between:

```
chmod a–w file
```

which removes all write permissions, and:

```
chmod –– –w file
```

which removes write permissions that would be allowed if **file** was created with the same *umask*.

Portable applications should never assume that they know how the set-user-ID and set-group-ID bits on directories are interpreted.

EXAMPLES

Mode	Results
a+=	Equivalent to *a*+,*a*=; clears all file mode bits.
go+–w	Equivalent to *go*+,*go*–*w*; clears group and other write bits.
g=*o*–*w*	Equivalent to *g*=*o*,*g*–*w*; sets group bit to match other bits and then clears group write bit.
g–*r*+*w*	Equivalent to *g*–*r*,*g*+*w*; clears group read bit and sets group write bit.
=*g*	Sets owner bits to match group bits and sets other bits to match group bits.

RATIONALE

The functionality of *chmod* is described substantially through references to concepts defined in the System Interfaces volume of IEEE Std. 1003.1-200x. In this way, there is less duplication of effort required for describing the interactions of permissions. However, the behavior of this utility is not described in terms of the *chmod*( ) function from the System Interfaces volume of IEEE Std. 1003.1-200x because that specification requires certain side effects upon alternate file access control mechanisms that might not be appropriate, depending on the implementation.

Implementations that support mandatory file and record locking as specified by the 1984 /usr/group standard historically used the combination of set-group-ID bit set and group execute bit clear to indicate mandatory locking. This condition is usually set or cleared with the symbolic mode **perm** symbol **l** instead of the **perm** symbols **s** and **x** so that the mandatory locking mode is not changed without explicit indication that that was what the user intended. Therefore, the details on how the implementation treats these conditions must be defined in the documentation. This volume of IEEE Std. 1003.1-200x does not require mandatory locking (nor does the System Interfaces volume of IEEE Std. 1003.1-200x), but does allow it as an extension. However, this volume of IEEE Std. 1003.1-200x does require that the *ls* and *chmod* utilities work

consistently in this area. If *ls* **–l** *file* indicates that the set-group-ID bit is set, *chmod* **g–s** *file* must clear it (assuming appropriate privileges exist to change modes).

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. This problem is avoided here by specifying only 0 and >0 as exit values.

The System Interfaces volume of IEEE Std. 1003.1-200x indicates that implementation-defined restrictions may cause the S_ISUID and S_ISGID bits to be ignored. This volume of IEEE Std. 1003.1-200x allows the *chmod* utility to choose to modify these bits before calling *chmod*( ) (or some function providing equivalent capabilities) for non-regular files. Among other things, this allows implementations that use the set-user-ID and set-group-ID bits on directories to enable extended features to handle these extensions in an intelligent manner.

The **X perm** symbol was adopted from BSD-based systems because it provides commonly desired functionality when doing recursive (**–R** option) modifications. Similar functionality is not provided by the *find* utility. Historical BSD versions of *chmod*, however, only supported **X** with *op*+; it has been extended in this volume of IEEE Std. 1003.1-200x because it is also useful with *op*=. (It has also been added for *op*– even though it duplicates **x**, in this case, because it is intuitive and easier to explain.)

The grammar was extended with the *permcopy* non-terminal to allow historical-practice forms of symbolic modes like **o**=**u** –**g** (that is, set the ‘‘other’’ permissions to the permissions of ‘‘owner’’ minus the permissions of ‘‘group’’).

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Octal modes have been kept and made mandatory despite being marked obsolescent in the previous version of this volume of IEEE Std. 1003.1-200x.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to ‘‘Default.’’.

9307 **NAME**

9308 chown — change the file ownership

9309 **SYNOPSIS**

9310 `chown –hR` *owner*`[:`*group*`]` *file* `...`

9311 `chown –R [–H | –L | –P ]` *owner*`[:`*group*`]` *file* `...`

9312 **DESCRIPTION**

9313 The *chown* utility shall set the user ID of the file named by each *file* operand to the user ID
9314 specified by the *owner* operand.

9315 For each *file* operand, it shall perform actions equivalent to the *chown*( ) function defined in the
9316 System Interfaces volume of IEEE Std. 1003.1-200x, called with the following arguments:

9317 1. The *file* operand shall be used as the *path* argument.

9318 2. The user ID indicated by the *owner* portion of the first operand shall be used as the *owner*
9319 argument.

9320 3. If the *group* portion of the first operand is given, the group ID indicated by it shall be used
9321 as the *group* argument; otherwise, the group ID of the file shall be used as the *group*
9322 argument.

9323 Unless *chown* is invoked by a process with appropriate privileges, the set-user-ID and set-
9324 group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and
9325 set-group-ID bits of other file types may be cleared.

9326 **OPTIONS**

9327 The *chown* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
9328 12.2, Utility Syntax Guidelines.

9329 The following options shall be supported by the implementation:

9330 **–h** If the system supports user IDs for symbolic links, for each *file* operand that names
9331 a file of type symbolic link, *chown* shall attempt to set the user ID of the symbolic
9332 link. If the system supports group IDs for symbolic links, and a group ID was
9333 specified, for each *file* operand that names a file of type symbolic link, *chown* shall
9334 attempt to set the group ID of the symbolic link. If the system does not support
9335 user or group IDs for symbolic links, for each *file* operand that names a file of type
9336 symbolic link, *chown* shall do nothing more with the current file and shall go on to
9337 any remaining files.

9338 **–H** If the **–R** option is specified and a symbolic link referencing a file of type directory
9339 is specified on the command line, *chown* shall change the user ID (and group ID, if
9340 specified) of the directory referenced by the symbolic link and all files in the file
9341 hierarchy below it.

9342 **–L** If the **–R** option is specified and a symbolic link referencing a file of type directory
9343 is specified on the command line or encountered during the traversal of a file
9344 hierarchy, *chown* shall change the user ID (and group ID, if specified) of the
9345 directory referenced by the symbolic link and all files in the file hierarchy below it.

9346 **–P** If the **–R** option is specified and a symbolic link is specified on the command line
9347 or encountered during the traversal of a file hierarchy, *chown* shall change the
9348 owner ID (and group ID, if specified) of the symbolic link if the system supports
9349 this operation. The *chown* utility shall not follow the symbolic link to any other
9350 part of the file hierarchy.

–R Recursively change file user and group IDs. For each *file* operand that names a directory, *chown* shall change the user ID (and group ID, if specified) of the directory and all files in the file hierarchy below it. Unless a **–H**, **–L**, or **–P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

*owner***[**:*group***]** A user ID and optional group ID to be assigned to *file*. The application shall ensure that the *owner* portion of this operand is a user name from the user database or a numeric user ID. Either specifies a user ID to be given to each file named by one of the *file* operands. If a numeric *owner* operand exists in the user database as a user name, the user ID number associated with that user name is used as the user ID. Similarly, if the *group* portion of this operand is present, it shall be a group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name shall be used as the group ID.

file A path name of a file whose user ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chown*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some systems restrict the use of *chown* to a user with appropriate privileges.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. These are masked by specifying only 0 and >0 as exit values.

The functionality of *chown* is described substantially through references to functions in the System Interfaces volume of IEEE Std. 1003.1-200x. In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

The 4.3 BSD method of specifying both owner and group was included in this volume of IEEE Std. 1003.1-200x because:

- There are cases where the desired end condition could not be achieved using the *chgrp* and *chown* (that only changed the user ID) utilities. (If the current owner is not a member of the desired group and the desired owner is not a member of the current group, the *chown*( ) function could fail unless both owner and group are changed at the same time.)
- Even if they could be changed independently, in cases where both are being changed, there is a 100% performance penalty caused by being forced to invoke both utilities.

The BSD syntax *user*[.*group*] was changed to *user*[:*group*] in this volume of IEEE Std. 1003.1-200x because the period is a valid character in login names (as specified by the Base Definitions volume of IEEE Std. 1003.1-200x, login names consist of characters in the portable file name character set). The colon character was chosen as the replacement for the period character because it would never be allowed as a character in a user name or group name on historical implementations.

The **–R** option is considered by some observers as an undesirable departure from the historical UNIX system tools approach; since a tool, *find*, already exists to recurse over directories, there seemed to be no good reason to require other tools to have to duplicate that functionality. However, the **–R** option was deemed an important user convenience, is far more efficient than

forking a separate process for each element of the directory hierarchy, and is in widespread historical use.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

New options **–h**, **–H**, **–L**, and **–P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section is changed to ‘‘Default.’’.

NAME

cksum — write file checksums and sizes

SYNOPSIS

```
cksum [file ...]
```

DESCRIPTION

The *cksum* utility shall calculate and write to standard output a cyclic redundancy check (CRC) for each input file, and also write to standard output the number of octets in each file. The CRC used is based on the polynomial used for CRC error checking in the ISO/IEC 8802-3:1996 standard (Ethernet).

The encoding for the CRC checksum is defined by the generating polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Mathematically, the CRC value corresponding to a given file shall be defined by the following procedure:

1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer shall be used.
2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31.
3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.
4. The bit sequence is complemented and the result is the CRC.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file A path name of a file to be checked. If no *file* operands are specified, the standard input is used.

STDIN

The standard input is used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cksum*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

For each file processed successfully, the *cksum* utility shall write in the following format:

"%u %d %s\n", <*checksum*>, <*# of octets*>, <*pathname*>

If no *file* operand was specified, the path name and its leading <space> shall be omitted.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All files were processed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *cksum* utility is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are small; deliberate deception is difficult, but probably not impossible.

Although input files to *cksum* can be any type, the results need not be what would be expected on character special device files or on file types not described by the System Interfaces volume of IEEE Std. 1003.1-200x. Since this volume of IEEE Std. 1003.1-200x does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.

The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as moving 8-bit characters into 9-bit bytes or changing little-endian byte ordering to big-endian), identical CRC values cannot be expected. Implementations performing such transformations may extend *cksum* to handle such situations.

EXAMPLES

None.

RATIONALE

The following C-language program can be used as a model to describe the algorithm. It assumes that a **char** is one octet. It also assumes that the entire file is available for one pass through the function. This was done for simplicity in demonstrating the algorithm, rather than as an implementation model.

unsigned long memcrc(const unsigned char *b, size_t n)
{
/*  Input arguments:
 *  const char*   b == byte sequence to checksum
 *  size_t        n == length of sequence
 */
    register unsigned   i, c, s = 0;

    for (i = n; i > 0; --i) {
        c = (unsigned)(*b++);
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    /* Extend with the length of the string. */
    while (n != 0) {
        c = n & 0377;
        n >>= 8;
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
    }

    return ~s;
}
```

The historical practice of writing the number of ‘‘blocks’’ has been changed to writing the number of octets, since the latter is not only more useful, but also since historical implementations have not been consistent in defining what a ‘‘block’’ meant. Octets are used instead of bytes because bytes can differ in size between systems.

The algorithm used was selected to increase the operational robustness of *cksum*. Neither the System V nor BSD *sum* algorithm was selected. Since each of these was different and each was the default behavior on those systems, no realistic compromise was available if either were selected—some set of historical applications would break. Therefore, the name was changed to *cksum*. Although the historical *sum* commands will probably continue to be provided for many years, programs designed for portability across systems should use the new name.

The algorithm selected is based on that used by the ISO / IEC 8802-3: 1996 standard (Ethernet) for the frame check sequence field. The algorithm used does not match the technical definition of a *checksum*; the term is used for historical reasons. The length of the file is included in the CRC calculation because this parallels inclusion of a length field by Ethernet in its CRC, but also because it guards against inadvertent collisions between files that begin with different series of zero octets. The chance that two different files produce identical CRCs is much greater when their lengths are not considered. Keeping the length and the checksum of the file itself separate would yield a slightly more robust algorithm, but historical usage has always been that a single number (the checksum as printed) represents the signature of the file. It was decided that

historical usage was the more important consideration.

Early proposals contained modifications to the Ethernet algorithm that involved extracting table values whenever an intermediate result became zero. This was demonstrated to be less robust than the current method and mathematically difficult to describe or justify.

The calculation used is identical to that given in pseudo-code in the referenced Sarwate article. The pseudo-code rendition is:

```
X <– 0; Y <– 0;
for i <– m –1 step –1 until 0 do
    begin
    T <– X(1) ^ A[i];
    X(1) <– X(0); X(0) <– Y(1); Y(1) <– Y(0); Y(0) <– 0;
    comment: f[T] and f'[T] denote the T-th words in the
        table f and f' ;
    X <– X ^ f[T]; Y <– Y ^ f'[T];
    end
```

The pseudo-code is reproduced exactly as given; however, note that in the case of *cksum*, **A[i]** represents a byte of the file, the words **X** and **Y** are treated as a single 32-bit value, and the tables **f** and **f'** are a single table containing 32-bit values.

The referenced Sarwate article also discusses generating the table.

CHANGE HISTORY

First released in Issue 4.

NAME

cmp — compare two files

SYNOPSIS

```
cmp [ –l | –s ] file1 file2
```

DESCRIPTION

The *cmp* utility shall compare two files. The *cmp* utility writes no output if the files are the same. Under default options, if they differ, it shall write to standard output the byte and line number at which the first difference occurred. Bytes and lines shall be numbered beginning with 1.

OPTIONS

The *cmp* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–l (Lowercase ell.) Write the byte number (decimal) and the differing bytes (octal) for each difference.

–s Write nothing for differing files; return exit status only.

OPERANDS

The following operands shall be supported:

file1 A path name of the first file to be compared. If *file1* is `'–'`, the standard input shall be used.

file2 A path name of the second file to be compared. If *file2* is `'–'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or refer to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if the *file1* or *file2* operand refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cmp*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

9706 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

9707 **ASYNCHRONOUS EVENTS**
9708 Default.

9709 **STDOUT**
9710 In the POSIX locale, results of the comparison shall be written to standard output. When no
9711 options are used, the format shall be:

9712 `"%s %s differ: char %d, line %d\n", file1, file2,`
9713 `    <byte number>, <line number>`

9714 When the **–l** option is used, the format shall be:

9715 `"%d %o %o\n", <byte number>, <differing byte>,`
9716 `    <differing byte>`

9717 for each byte that differs. The first <*differing byte*> number is from *file1* while the second is from
9718 *file2*. In both cases, <*byte number*> shall be relative to the beginning of the file, beginning with 1.

9719 No output shall be written to standard output when the **–s** option is used.

9720 **STDERR**
9721 Used only for diagnostic messages. If *file1* and *file2* are identical for the entire length of the
9722 shorter file, in the POSIX locale the following diagnostic message shall be written, unless the **–s**
9723 option is specified:

9724 `"cmp: EOF on %s%s\n", <name of shorter file>, <additional info>`

9725 The <*additional info*> field shall either be null or a string that starts with a <blank> character and
9726 contains no <newline> characters. Some systems report on the number of lines in this case.

9727 **OUTPUT FILES**
9728 None.

9729 **EXTENDED DESCRIPTION**
9730 None.

9731 **EXIT STATUS**
9732 The following exit values shall be returned:

9733 0 The files are identical.

9734 1 The files are different; this includes the case where one file is identical to the first part of the
9735 other.

9736 >1 An error occurred.

9737 **CONSEQUENCES OF ERRORS**
9738 Default.

9739 **APPLICATION USAGE**
9740 Although input files to *cmp* can be any type, the results might not be what would be expected on
9741 character special device files or on file types not described by the System Interfaces volume of
9742 IEEE Std. 1003.1-200x. Since this volume of IEEE Std. 1003.1-200x does not specify the block size
9743 used when doing input, comparisons of character special files need not compare all of the data
9744 in those files.

9745 For files which are not text files, line numbers simply reflect the presence of a <newline>
9746 character, without any implication that the file is organized into lines.

EXAMPLES

None.

RATIONALE

The global language in Section 1.11 (on page 2224) indicates that using two mutually-exclusive options together produces unspecified results. Some System V implementations consider the option usage:

```
cmp –l –s ...
```

to be an error. They also treat:

```
cmp –s –l ...
```

as if no options were specified. Both of these behaviors are considered bugs, but are allowed.

The word **char** in the standard output format comes from historical usage, even though it is actually a byte number. When *cmp* is supported in other locales, implementations are encouraged to use the word *byte* or its equivalent in another language. Users should not interpret this difference to indicate that the functionality of the utility changed between locales.

Some systems report on the number of lines in the identical-but-shorter file case. This is allowed by the inclusion of the <*additional info*> fields in the output format. The restriction on having a leading <blank> and no <newline>s is to make parsing for the file name easier. It is recognized that some file names containing white-space characters make parsing difficult anyway, but the restriction does aid programs used on systems where the names are predominantly well behaved.

FUTURE DIRECTIONS

None.

SEE ALSO

comm, *diff*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

comm — select or reject lines common to two files

SYNOPSIS

```
comm [–123] file1 file2
```

DESCRIPTION

The *comm* utility shall read *file1* and *file2*, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in *file1*, lines only in *file2*, and lines in both files.

If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.

OPTIONS

The *comm* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–1 Suppress the output column of lines unique to *file1*.

–2 Suppress the output column of lines unique to *file2*.

–3 Suppress the output column of lines duplicated in *file1* and *file2*.

OPERANDS

The following operands shall be supported:

file1 A path name of the first file to be compared. If *file1* is `'–'`, the standard input is used.

file2 A path name of the second file to be compared. If *file2* is `'–'`, the standard input is used.

If both *file1* and *file2* refer to standard input or to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if one of the *file1* or *file2* operands refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *comm*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the collating sequence *comm* expects to have been used when the input files were sorted.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *comm* utility shall produce output depending on the options selected. If the **–1**, **–2**, and **–3** options are all selected, *comm* shall write nothing to standard output.

If the **–1** option is not selected, lines contained only in *file1* shall be written using the format:

`"%s\n", <line in file1>`

If the **–2** option is not selected, lines contained only in *file2* are written using the format:

`"%s%s\n", <lead>, <line in file2>`

where the string <*lead*> is as follows:

<tab> The **–1** option is not selected.

null string The **–1** option is selected.

If the **–3** option is not selected, lines contained in both files shall be written using the format:

`"%s%s\n", <lead>, <line in both>`

where the string <*lead*> is as follows:

<tab><tab> Neither the **–1** nor the **–2** option is selected.

<tab> Exactly one of the **–1** and **–2** options is selected.

null string Both the **–1** and **–2** options are selected.

If the input files were ordered according to the collating sequence of the current locale, the lines written shall be in the collating sequence of the original lines.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were successfully output as specified.

>0 An error occurred.

9854 **CONSEQUENCES OF ERRORS**

9855 Default.

9856 **APPLICATION USAGE**

9857 If the input files are not properly presorted, the output of *comm* might not be useful.

9858 **EXAMPLES**

9859 If a file named **xcu** contains a sorted list of the utilities in this volume of IEEE Std. 1003.1-200x, a
9860 file named **xpg3** contains a sorted list of the utilities specified in the X/Open Portability Guide,
9861 Issue 3, and a file named **svid89** contains a sorted list of the utilities in the System V Interface
9862 Definition Third Edition:

9863 `comm –23 xcu xpg3 | comm –23 – svid89`

9864 would print a list of utilities in this volume of IEEE Std. 1003.1-200x not specified by either of the
9865 other documents:

9866 `comm –12 xcu xpg3 | comm –12 – svid89`

9867 would print a list of utilities specified by all three documents, and:

9868 `comm –12 xpg3 svid89 | comm –23 – xcu`

9869 would print a list of utilities specified by both XPG3 and the SVID, but not specified in this
9870 volume of IEEE Std. 1003.1-200x.

9871 **RATIONALE**

9872 None.

9873 **FUTURE DIRECTIONS**

9874 None.

9881 **Issue 6**

9882 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

command — execute a simple command

SYNOPSIS

```
command [–p] command_name [argument ...]
command [ –v | –V ] command_name
```

UP

DESCRIPTION

The *command* utility shall cause the shell to treat the arguments as a simple command, suppressing the shell function lookup that is described in Section 2.9.1.1 (on page 2257), item 1b.

If the *command_name* is the same as the name of one of the special built-in utilities, the special properties in the enumerated list at the beginning of Section 2.15 (on page 2276) shall not occur. In every other respect, if *command_name* is not the name of a function, the effect of *command* shall be the same as omitting *command*.

On systems supporting the User Portability Utilities option, the *command* utility also shall provide information concerning how a command name is interpreted by the shell; see **–v** and **–V**.

OPTIONS

The *command* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–p Perform the command search using a default value for *PATH* that is guaranteed to find all of the standard utilities.

–v (On systems supporting the User Portability Utilities option.) Write a string to standard output that indicates the path name or command that will be used by the shell, in the current shell execution environment (see Section 2.13 (on page 2273)), to invoke *command_name*.

- Utilities, regular built-in utilities, *command_name*s including a slash character, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1 (on page 2257)), shall be written as absolute path names.
- Shell functions, special built-in utilities, regular built-in utilities not associated with a *PATH* search, and shell reserved words shall be written as just their names.
- An alias shall be written as a command line that represents its alias definition.
- Otherwise, no output shall be written and the exit status shall reflect that the name was not found.

–V (On systems supporting the User Portability Utilities option.) Write a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment (see Section 2.13 (on page 2273)). Although the format of this string is unspecified, it shall indicate in which of the following categories *command_name* falls and shall include the information stated:

- Utilities, regular built-in utilities, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1 (on page 2257)), shall be identified as such and include the absolute path name in the

string.

- Other shell functions shall be identified as functions.
- Aliases shall be identified as aliases and their definitions included in the string.
- Special built-in utilities shall be identified as special built-in utilities.
- Regular built-in utilities not associated with a *PATH* search shall be identified as regular built-in utilities. (The term ‘‘regular’’ need not be used.)
- Shell reserved words shall be identified as reserved words.

OPERANDS

The following operands shall be supported:

argument One of the strings treated as an argument to *command_name*.

command_name
The name of a utility or a special built-in utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *command*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path used during the command search described in Section 2.9.1.1 (on page 2257), except as described under the **–p** option.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–v** option is specified, standard output shall be formatted as:

`"%s\n", <pathname or command>`

When the **–V** option is specified, standard output shall be formatted as:

```
"%s\n", <unspecified>
```

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

When the **–v** or **–V** options are specified, the following exit values shall be returned:

0 Successful completion.

>0 The *command_name* could not be found or an error occurred.

Otherwise, the following exit values shall be returned:

126 The utility specified by *command_name* was found but could not be invoked.

127 An error occurred in the *command* utility or the utility specified by *command_name* could not be found.

Otherwise, the exit status of *command* shall be that of the simple command specified by the arguments to *command*.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The order for command search allows functions to override regular built-ins and path searches. This utility is necessary to allow functions that have the same name as a utility to call the utility (instead of a recursive call to the function).

The system default path is available using *getconf*; however, since *getconf* may need to have the *PATH* set up before it can be called itself, the following can be used:

```
command –p getconf _CS_PATH
```

There are some advantages to suppressing the special characteristics of special built-ins on occasion. For example:

```
command exec > unwritable-file
```

does not cause a non-interactive script to abort, so that the output status can be checked by the script.

The *command*, *env*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked utility exited with an error indication’’. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

Since the **–v** and **–V** options of *command* produce output in relation to the current shell execution environment, *command* is generally provided as a shell regular built-in. If it is called in a subshell

or separate utility execution environment, such as one of the following:

```
(PATH=foo command –v)
 nohup command –v
```

it does not necessarily produce correct results. For example, when called with *nohup* or an *exec* function, in a separate utility execution environment, most implementations are not able to identify aliases, functions, or special built-ins.

Two types of regular built-ins could be encountered on a system and these are described separately by *command*. The description of command search in Section 2.9.1.1 (on page 2257) allows for a standard utility to be implemented as a regular built-in as long as it is found in the appropriate place in a *PATH* search. So, for example, *command* –**v** *true* might yield **/bin/true** or some similar path name. Other implementation-defined utilities that are not defined by this volume of IEEE Std. 1003.1-200x might exist only as built-ins and have no path name associated with them. These produce output identified as (regular) built-ins. Applications encountering these are not able to count on *exec*ing them, using them with *nohup*, overriding them with a different *PATH*, and so on.

EXAMPLES

1. Make a version of *cd* that always prints out the new working directory exactly once:

   ```
   cd() {
       command cd "$@" >/dev/null
       pwd
   }
   ```

2. Start off a ‘‘secure shell script’’ in which the script avoids being spoofed by its parent:

   ```
   IFS='
   '
   #    The preceding value should be <space><tab><newline>.
   #    Set IFS to its default value.

   \unalias –a
   #    Unset all possible aliases.
   #    Note that unalias is escaped to prevent an alias
   #    being used for unalias.

   unset –f command
   #    Ensure command is not a user function.

   PATH="$(command –p getconf _CS_PATH):$PATH"
   #    Put on a reliable PATH prefix.

   #    ...
   ```

   At this point, given correct permissions on the directories called by *PATH*, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this volume of IEEE Std. 1003.1-200x, but it is not prohibited as an extension. For example, the *ENV* variable precedes the invocation of the script with a user start-up script. Such a script could define functions to spoof the application.

RATIONALE

Since *command* is a regular built-in utility it is always found prior to the *PATH* search.

There is nothing in the description of *command* that implies the command line is parsed any differently from that of any other simple command. For example:

```
command a | b ; c
```

is not parsed in any special way that causes `'|'` or `';'` to be treated other than a pipe operator or semicolon or that prevents function lookup on **b** or **c**.

The *command* utility is somewhat similar to the Eighth Edition shell *builtin* command, but since *command* also goes to the file system to search for utilities, the name *builtin* would not be intuitive.

The *command* utility is most likely to be provided as a regular built-in. It is not listed as a special built-in for the following reasons:

- The removal of exportable functions made the special precedence of a special built-in unnecessary.
- A special built-in has special properties (see Section 2.15 (on page 2276)) that were inappropriate for invoking other utilities. For example, two commands such as:

  ```
  date > unwritable-file
  ```

  ```
  command date > unwritable-file
  ```

  would have entirely different results; in a non-interactive script, the former would continue to execute the next command, the latter would abort. Introducing this semantic difference along with suppressing functions was seen to be non-intuitive.

The **–p** option is present because it is useful to be able to ensure a safe path search that finds all the POSIX Shell and Utilities standard utilities. This search might not be identical to the one that occurs through one of the POSIX System Interfaces *exec* functions when *PATH* is unset. At the very least, this feature is required to allow the script to access the correct version of *getconf* so that the value of the default path can be accurately retrieved.

The *command* **–v** and **–V** options were added to satisfy requirements from users that are currently accomplished by three different historical utilities: *type* in the System V shell, *whence* in the KornShell, and *which* in the C shell. Since there is no historical agreement on how and what to accomplish here, the POSIX *command* utility was enhanced and the historical utilities were left unmodified. The C shell *which* merely conducts a path search. The KornShell *whence* is more elaborate—in addition to the categories required by POSIX, it also reports on tracked aliases, exported aliases, and undefined functions.

The output format of **–V** was left mostly unspecified because human users are its only audience. Applications should not be written to care about this information; they can use the output of **–v** to differentiate between various types of commands, but the additional information that may be emitted by the more verbose **–V** is not needed and should not be arbitrarily constrained in its verbosity or localization for application parsing reasons.

10096 **CHANGE HISTORY**

10097 First released in Issue 4.

10098 **NAME**

10099 compress — compress data

10100 **SYNOPSIS**

10101 XSI `compress [–fv][–b bits][file ...]`

10102 `compress [–cfv][–b bits][file]`

10103

10104 **DESCRIPTION**

10105 ***Notes to Reviewers***

10106 *This section with side shading will not appear in the final copy. - Ed.*

10107 We need to cite the patent number for Lempel-Ziv coding; if anyone knows what it is, please let
10108 us know.

10109 The *compress* utility shall attempt to reduce the size of the named files by using adaptive
10110 Lempel-Ziv coding algorithm. On systems not supporting adaptive Lempel-Ziv coding
10111 algorithm, the input files shall not be changed and an error value greater than two shall be
10112 returned. Except when the output is to the standard output, each file shall be replaced by one
10113 with the extension **.Z**. If the invoking process has appropriate privileges, the ownership, modes,
10114 access time, and modification time of the original file are preserved. If appending the **.Z** to the
10115 file name would make the name exceed {NAME_MAX} bytes, the command shall fail. If no files
10116 are specified, the standard input shall be compressed to the standard output.

10117 **OPTIONS**

10118 The *compress* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x,
10119 Section 12.2, Utility Syntax Guidelines.

10120 The following options shall be supported:

10121 **–b** *bits* Specify the maximum number of bits to use in a code. For a portable application,
10122 the *bits* argument shall be:

10123 `9 <= bits <= 14`

10124 The implementation may allow *bits* values of greater than 14. The default is 14, 15,
10125 or 16.

10126 **–c** Cause *compress* to write to the standard output; the input file is not changed, and
10127 no **.Z** files are created.

10128 **–f** Force compression of *file*, even if it does not actually reduce the size of the file, or if
10129 the corresponding *file***.Z** file already exists. If the **–f** option is not given, and the
10130 process is not running in the background, the user is prompted as to whether an
10131 existing *file***.Z** file should be overwritten.

10132 **–v** Write the percentage reduction of each file to standard error.

10133 **OPERANDS**

10134 The following operand shall be supported:

10135 *file* A path name of a file to be compressed.

10136 **STDIN**

10137 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

INPUT FILES

If *file* operands are specified, the input files contain the data to be compressed.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *compress*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no *file* operands are specified, or if a *file* operand is '**−**', or if the **−c** option is specified, the standard output contains the compressed output.

STDERR

Used for all diagnostic and prompt messages and the output from **−v**.

OUTPUT FILES

The output files shall contain the compressed output. The format of compressed files is unspecified and interchange of such files between implementations (including access via unspecified file sharing mechanisms) is not required by IEEE Std. 1003.1-200x.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 An error occurred.

2 One or more files were not compressed because they would have increased in size (and the **−f** option was not specified).

>2 An error occurred.

CONSEQUENCES OF ERRORS

The input file shall remain unmodified.

APPLICATION USAGE

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50-60%. Compression is generally much better than that achieved by Huffman coding or adaptive Huffman coding (*compact*), and takes less time to compute.

Although *compress* strictly follows the default actions upon receipt of a signal or when an error occurs, some unexpected results may occur. In some implementations it is likely that a partially compressed file is left in place, alongside its uncompressed input file. Since the general operation of *compress* is to delete the uncompressed file only after the **.Z** file has been successfully filled, an application should always carefully check the exit status of *compress* before arbitrarily deleting files that have like-named neighbors with **.Z** suffixes.

The limit of 14 on the *bits* option-argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some systems based on 16-bit architectures cannot support 15 or 16-bit uncompression.

CHANGE HISTORY

First released in Issue 4.

Issue 4, Version 2

The DESCRIPTION section is clarified to state that the ownership, modes, access time, and modification time of the original file are preserved if the invoking process has appropriate privileges.

The STDOUT section includes the case where a *file* operand is '–'.

Issue 6

The normative text is reworded to avoid use of the term ''must'' for application requirements.

An error case is added for systems not supporting adaptive Lempel-Ziv coding.

10210 **NAME**

10211 cp — copy files

10212 **SYNOPSIS**

10213 `cp [–fip] source_file target_file`

10214 `cp [–fip] source_file ... target`

10215 `cp –R [–H | –L | –P][–fip] source_file ... target`

10216 OB `cp –r [–H | –L | –P][–fip] source_file ... target` |

10217 **DESCRIPTION** |

10218 The first synopsis form is denoted by two operands, neither of which are existing files of type
10219 directory. The *cp* utility shall copy the contents of *source_file* (or, if *source_file* is a file of type
10220 symbolic link, the contents of the file referenced by *source_file*) to the destination path named by
10221 *target_file*.

10222 The second synopsis form is denoted by two or more operands where the **–R** or **–r** options are
10223 not specified and the first synopsis form is not applicable. It shall be an error if any *source_file* is a
10224 file of type directory, if *target* does not exist, or if *target* is a file of a type defined by the System
10225 Interfaces volume of IEEE Std. 1003.1-200x, but is not a file of type directory. The *cp* utility shall
10226 copy the contents of each *source_file* (or, if *source_file* is a file of type symbolic link, the contents
10227 of the file referenced by *source_file*) to the destination path named by the concatenation of *target*,
10228 a slash character, and the last component of *source_file*.

10229 The third and fourth synopsis forms are denoted by two or more operands where the **–R** or **–r**
10230 options are specified. The *cp* utility shall copy each file in the file hierarchy rooted in each
10231 *source_file* to a destination path named as follows.

10232 If *target* exists and is a file of type directory, the name of the corresponding destination path for
10233 each file in the file hierarchy shall be the concatenation of *target*, a slash character, and the path
10234 name of the file relative to the directory containing *source_file*.

10235 If *target* does not exist and two operands are specified, the name of the corresponding
10236 destination path for *source_file* shall be *target*; the name of the corresponding destination path for
10237 all other files in the file hierarchy shall be the concatenation of *target*, a slash character, and the
10238 path name of the file relative to *source_file*.

10239 It shall be an error if *target* does not exist and more than two operands are specified, or if *target*
10240 exists and is a file of a type defined by the System Interfaces volume of IEEE Std. 1003.1-200x,
10241 but is not a file of type directory.

10242 In the following description, the term *dest_file* refers to the file named by the destination path.
10243 The term *source_file* refers to the file that is being copied, whether specified as an operand or a
10244 file in a file hierarchy rooted in a *source_file* operand. If *source_file* is a file of type symbolic link:

10245 • If neither the **–R** nor **–r** options were specified, *cp* shall take actions based on the type and
10246 contents of the file referenced by the symbolic link, and not by the symbolic link itself.

10247 • If the **–R** option was specified:

10248 — If none of the options **–H**, **–L**, nor **–P** were specified, it is unspecified which of **–H**, **–L**, or
10249 **–P** will be used as a default.

10250 — If the **–H** option was specified, *cp* shall take actions based on the type and contents of the
10251 file referenced by any symbolic link specified as a *source_file* operand.

10252 — If the **–L** option was specified, *cp* shall take actions based on the type and contents of the
10253 file referenced by any symbolic link specified as a *source_file* operand or any symbolic

links encountered during traversal of a file hierarchy.

— If the **–P** option was specified, *cp* shall copy any symbolic link specified as a *source_file* operand and any symbolic links encountered during traversal of a file hierarchy, and shall not follow any symbolic links.

- If the **–r** option was specified, the behavior is implementation-defined.

For each *source_file*, the following steps shall be taken:

1. If *source_file* references the same file as *dest_file*, *cp* may write a diagnostic message to standard error; it shall do nothing more with *source_file* and shall go on to any remaining files.
2. If *source_file* is of type directory, the following steps shall be taken:
   a. If neither the **–R** or **–r** options were specified, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.
   b. If *source_file* was not specified as an operand and *source_file* is dot or dot-dot, *cp* shall do nothing more with *source_file* and go on to any remaining files.
   c. If *dest_file* exists and it is a file type not specified by the System Interfaces volume of IEEE Std. 1003.1-200x, the behavior is implementation-defined.
   d. If *dest_file* exists and it is not of type directory, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file* or any files below *source_file* in the file hierarchy, and go on to any remaining files.
   e. If the directory *dest_file* does not exist, it shall be created with file permission bits set to the same value as those of *source_file*, modified by the file creation mask of the user if the **–p** option was not specified, and then bitwise-inclusively OR'ed with S_IRWXU. If *dest_file* cannot be created, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files. It is unspecified if *cp* attempts to copy files in the file hierarchy rooted in *source_file*.
   f. The files in the directory *source_file* shall be copied to the directory *dest_file*, taking the four steps [1-4] listed here with the files as *source_file*s.
   g. If *dest_file* was created, its file permission bits shall be changed (if necessary) to be the same as those of *source_file*, modified by the file creation mask of the user if the **–p** option was not specified.
   h. The *cp* utility shall do nothing more with *source_file* and go on to any remaining files.
3. If *source_file* is of type regular file, the following steps shall be taken:
   a. If *dest_file* exists, the following steps shall be taken:
      i. If the **–i** option is in effect, the *cp* utility shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *cp* shall do nothing more with *source_file* and go on to any remaining files.
      ii. A file descriptor for *dest_file* shall be obtained by performing actions equivalent to the *open*() function defined in the System Interfaces volume of IEEE Std. 1003.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_TRUNC as the *oflag* argument.
      iii. If the attempt to obtain a file descriptor fails and the **–f** option is in effect, *cp* shall attempt to remove the file by performing actions equivalent to the *unlink*() function defined in the System Interfaces volume of

IEEE Std. 1003.1-200x called using *dest_file* as the *path* argument. If this attempt succeeds, *cp* shall continue with step 3b.

b. If *dest_file* does not exist, a file descriptor shall be obtained by performing actions equivalent to the *open*() function defined in the System Interfaces volume of IEEE Std. 1003.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_CREAT as the *oflag* argument. The file permission bits of *source_file* shall be the *mode* argument.

c. If the attempt to obtain a file descriptor fails, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

d. The contents of *source_file* shall be written to the file descriptor. Any write errors shall cause *cp* to write a diagnostic message to standard error and continue to step 3e.

e. The file descriptor shall be closed.

f. The *cp* utility shall do nothing more with *source_file*. If a write error occurred in step 3d, it is unspecified if *cp* continues with any remaining files. If no write error occurred in step 3d, *cp* shall go on to any remaining files.

4. Otherwise, the following steps shall be taken:

a. If the **–r** option was specified, the behavior is implementation-defined.

b. If the **–R** option was specified, the following steps shall be taken:

i. The *dest_file* shall be created with the same file type as *source_file*.

ii. If *source_file* is a file of type FIFO, the file permission bits shall be the same as those of *source_file*, modified by the file creation mask of the user if the **–p** option was not specified. Otherwise, the permissions, owner ID, and group ID of *dest_file* are implementation-defined.

If this creation fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

iii. If *source_file* is a file of type symbolic link, the path name contained in *dest_file* shall be the same as the path name contained in *source_file*.

If this fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

If the implementation provides additional or alternate access control mechanisms (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 4.1, File Access Permissions), their effect on copies of files is implementation-defined.

OPTIONS

The *cp* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f If a file descriptor for a destination file cannot be obtained, as described in step 3.a.ii., attempt to unlink the destination file and proceed.

–H Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

–i Write a prompt to standard error before copying to any existing destination file. If the response from the standard input is affirmative, the copy shall be attempted;

otherwise, it shall not.

–L Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic links encountered during traversal of a file hierarchy.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

A description of the **–P** option is needed. This is not in the IEEE P1003.2b draft standard.

–p Duplicate the following characteristics of each source file in the corresponding destination file:

1. The time of last data modification and time of last access. If this duplication fails for any reason, *cp* shall write a diagnostic message to standard error.
2. The user ID and group ID. If this duplication fails for any reason, it is unspecified whether *cp* writes a diagnostic message to standard error.
3. The file permission bits and the S_ISUID and S_ISGID bits. Other, implementation-defined, bits may be duplicated as well. If this duplication fails for any reason, *cp* shall write a diagnostic message to standard error.

If the user ID or the group ID cannot be duplicated, the file permission bits S_ISUID and S_ISGID shall be cleared. If these bits are present in the source file but are not duplicated in the destination file, it is unspecified whether *cp* writes a diagnostic message to standard error.

The order in which the preceding characteristics are duplicated is unspecified. The *dest_file* shall not be deleted if these characteristics cannot be preserved.

–R Copy file hierarchies.

OB **–r** Copy file hierarchies. The treatment of special files is implementation-defined.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

source_file A path name of a file to be copied.

target_file A path name of an existing or nonexistent file, used for the output when a single file is copied.

target A path name of a directory to contain the copied files.

STDIN

Used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

INPUT FILES

The input files specified as operands may be of any file type.

10378 **ENVIRONMENT VARIABLES**

10379 The following environment variables shall affect the execution of *cp*:

10380 *LANG* Provide a default value for the internationalization variables that are unset or null.
10381 If *LANG* is unset or null, the corresponding value from the implementation-
10382 defined default locale shall be used. If any of the internationalization variables
10383 contains an invalid setting, the utility shall behave as if none of the variables had
10384 been defined.

10385 *LC_ALL* If set to a non-empty string value, override the values of all the other
10386 internationalization variables.

10387 *LC_COLLATE*
10388 Determine the locale for the behavior of ranges, equivalence classes, and multi-
10389 character collating elements used in the extended regular expression defined for
10390 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

10391 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
10392 characters (for example, single-byte as opposed to multi-byte characters in
10393 arguments and input files) and the behavior of character classes used in the
10394 extended regular expression defined for the **yesexpr** locale keyword in the
10395 *LC_MESSAGES* category.

10396 *LC_MESSAGES*
10397 Determine the locale for the processing of affirmative responses that should be
10398 used to affect the format and contents of diagnostic messages written to standard
10399 error.

10400 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

10401 **ASYNCHRONOUS EVENTS**

10402 Default.

10403 **STDOUT**

10404 Not used.

10405 **STDERR**

10406 A prompt shall be written to standard error under the conditions specified in the DESCRIPTION
10407 section. The prompt shall contain the destination path name, but its format is otherwise
10408 unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

10409 **OUTPUT FILES**

10410 The output files may be of any type.

10411 **EXTENDED DESCRIPTION**

10412 None.

10413 **EXIT STATUS**

10414 The following exit values shall be returned:

10415 0 All files were copied successfully.

10416 >0 An error occurred.

10417 **CONSEQUENCES OF ERRORS**

10418 If *cp* is prematurely terminated by a signal or error, files or file hierarchies may be only partially
10419 copied and files and directories may have incorrect permissions or access and modification
10420 times.

APPLICATION USAGE

The difference between **–R** and **–r** is in the treatment by *cp* of file types other than regular and directory. The original **–r** flag, for historic reasons, does not handle special files any differently from regular files, but always reads the file and copies its contents. This has obvious problems in the presence of special file types; for example, character devices, FIFOs, and sockets. The **–R** option is intended to recreate the file hierarchy and the **–r** option supports historical practice. It was anticipated that a future version of this volume of IEEE Std. 1003.1-200x would deprecate the **–r** option, and for that reason, there has been no attempt to fix its behavior with respect to FIFOs or other file types where copying the file is clearly wrong. However, some systems support **–r** with the same abilities as the **–R** defined in this volume of IEEE Std. 1003.1-200x. To accommodate them as well as systems that do not, the differences between **–r** and **–R** are implementation-defined. Implementations may make them identical. The **–r** option is now marked obsolescent.

The set-user-ID and set-group-ID bits are explicitly cleared when files are created. This is to prevent users from creating programs that are set-user-ID or set-group-ID to them when copying files or to make set-user-ID or set-group-ID files accessible to new groups of users. For example, if a file is set-user-ID and the copy has a different group ID than the source, a new group of users has execute permission to a set-user-ID program than did previously. In particular, this is a problem for superusers copying users' trees.

EXAMPLES

None.

RATIONALE

The **–i** option exists on BSD systems, giving applications and users a way to avoid accidentally removing files when copying. Although the 4.3 BSD version does not prompt if the standard input is not a terminal, the standard developers decided that use of **–i** is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds on standard input.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application using the **–i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The **–p** option is historical practice on BSD systems, duplicating the time of last data modification and time of last access. This volume of IEEE Std. 1003.1-200x extends it to preserve the user and group IDs, as well as the file permissions. This requirement has obvious problems in that the directories are almost certainly modified after being copied. This volume of IEEE Std. 1003.1-200x requires that the modification times be preserved. The statement that the order in which the characteristics are duplicated is unspecified is to permit implementations to provide the maximum amount of security for the user. Implementations should take into account the obvious security issues involved in setting the owner, group, and mode in the wrong order or creating files with an owner, group, or mode different from the final value.

It is unspecified whether *cp* writes diagnostic messages when the user and group IDs cannot be set due to the widespread practice of users using **–p** to duplicate some portion of the file characteristics, indifferent to the duplication of others. Historic implementations only write diagnostic messages on errors other than [EPERM].

The **–r** option is historical practice on BSD and BSD-derived systems, copying file hierarchies as opposed to single files. This functionality is used heavily in historical applications, and its loss would significantly decrease consensus. The **–R** option was added as a close synonym to the **–r** option, selected for consistency with all other options in this volume of IEEE Std. 1003.1-200x

that do recursive directory descent.

When a failure occurs during the copying of a file hierarchy, *cp* is required to attempt to copy files that are on the same level in the hierarchy or above the file where the failure occurred. It is unspecified if *cp* shall attempt to copy files below the file where the failure occurred (which cannot succeed in any case).

Permissions, owners, and groups of created special file types have been deliberately left as implementation-defined. This is to allow systems to satisfy special requirements (for example, allowing users to create character special devices, but requiring them to be owned by a certain group). In general, it is strongly suggested that the permissions, owner, and group be the same as if the user had run the historical *mknod*, *ln*, or other utility to create the file. It is also probable that additional privileges are required to create block, character, or other implementation-defined special file types.

Additionally, the **–p** option explicitly requires that all set-user-ID and set-group-ID permissions be discarded if any of the owner or group IDs cannot be set. This is to keep users from unintentionally giving away special privilege when copying programs.

When creating regular files, historical versions of *cp* use the mode of the source file as modified by the file mode creation mask. Other choices would have been to use the mode of the source file unmodified by the creation mask or to use the same mode as would be given to a new file created by the user (plus the execution bits of the source file) and then modify it by the file mode creation mask. In the absence of any strong reason to change historic practice, it was in large part retained.

When creating directories, historical versions of *cp* use the mode of the source directory, plus read, write, and search bits for the owner, as modified by the file mode creation mask. This is done so that *cp* can copy trees where the user has read permission, but the owner does not. A side effect is that if the file creation mask denies the owner permissions, *cp* fails. Also, once the copy is done, historical versions of *cp* set the permissions on the created directory to be the same as the source directory, unmodified by the file creation mask.

This behavior has been modified so that *cp* is always able to create the contents of the directory, regardless of the file creation mask. After the copy is done, the permissions are set to be the same as the source directory, as modified by the file creation mask. This latter change from historical behavior is to prevent users from accidentally creating directories with permissions beyond those they would normally set and for consistency with the behavior of *cp* in creating files.

It is not a requirement that *cp* detect attempts to copy a file to itself; however, implementations are strongly encouraged to do so. Historical implementations have detected the attempt in most cases.

There are two methods of copying subtrees in this volume of IEEE Std. 1003.1-200x. The other method is described as part of the *pax* utility (see *pax* (on page 2910)). Both methods are historical practice. The *cp* utility provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy, while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

The wording allowing *cp* to copy a directory to implementation-defined file types not specified by the System Interfaces volume of IEEE Std. 1003.1-200x is provided so that implementations supporting symbolic links are not required to prohibit copying directories to symbolic links. Other extensions to the System Interfaces volume of IEEE Std. 1003.1-200x file types may need to

use this loophole as well.

FUTURE DIRECTIONS

The **–r** option may be removed; use **–R** instead.

UP

```
crontab [file]
crontab [ –e | –l | –r ]
```

DESCRIPTION

The *crontab* utility shall create, replace, or edit a user's *crontab* entry; a crontab entry is a list of commands and the times at which they shall be executed. The new crontab entry can be input by specifying *file* or input from standard input if no *file* operand is specified, or by using an editor, if **–e** is specified.

Upon execution of a command from a crontab entry, the implementation shall supply a default environment, defining at least the following environment variables:

HOME A path name of the user's home directory.

LOGNAME The user's login name.

PATH A string representing a search path guaranteed to find all of the standard utilities.

SHELL A path name of the command interpreter. When *crontab* is invoked as specified by this volume of IEEE Std. 1003.1-200x, the value shall be a path name for *sh*.

The values of these variables when *crontab* is invoked as specified by this volume of IEEE Std. 1003.1-200x shall not affect the default values provided when the scheduled command is run.

If standard output and standard error are not redirected by commands executed from the crontab entry, any generated output or errors shall be mailed, via an implementation-defined method, to the user.

XSI

Users are permitted to use *crontab* if their names appear in the file **/usr/lib/cron/cron.allow**. If that file does not exist, the file **/usr/lib/cron/cron.deny** is checked to determine whether the user should be denied access to *crontab*. If neither file exists, only a process with appropriate privileges is allowed to submit a job. If only **cron.deny** exists and is empty, global usage is permitted. The **cron.allow** and **cron.deny** files consist of one user name per line.

OPTIONS

The *crontab* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–e Edit a copy of the invoking user's crontab entry, or create an empty entry to edit if the crontab entry does not exist. When editing is complete, the entry shall be installed as the user's crontab entry.

–l (The letter ell.) List the invoking user's crontab entry.

–r Remove the invoking user's crontab entry.

OPERANDS

The following operand shall be supported:

file The path name of a file that contains specifications, in the format defined in the INPUT FILES section, for crontab entries.

STDIN

See the INPUT FILES section.

INPUT FILES

In the POSIX locale, the user or application shall ensure that a crontab entry is a text file consisting of lines of six fields each. The fields shall be separated by <blank> characters. The first five fields shall be integer patterns that specify the following:

1. Minute (0-59)
2. Hour (0-23)
3. Day of the month (1-31)
4. Month of the year (1-12)
5. Day of the week (0-6 with 0=Sunday)

Each of these patterns can be either an asterisk (meaning all valid values), an element, or a list of elements separated by commas. An element shall be either a number or two numbers separated by a hyphen (meaning an inclusive range). The specification of days can be made by two fields (day of the month and day of the week). If month, day of month, and day of week are all asterisks, every day shall be matched. If either the month or day of month is specified as an element or list, but the day of week is an asterisk, the month and day of month fields shall specify the days that match. If both month and day of month are specified as asterisk, but day of week is an element or list, then only the specified days of the week match. Finally, if either the month or day of month is specified as an element or list, and the day of week is also specified as an element or list, then any day matching either the month and day of month, or the day of week, shall be matched.

The sixth field of a line in a crontab entry is a string that shall be executed by *sh* at the specified times. A percent sign character in this field shall be translated to a <newline> character. Any character preceded by a backslash (including the '%') shall cause that character to be treated literally. Only the first line (up to a '%' or end-of-line) of the command field shall be executed by the command interpreter. The other lines shall be made available to the command as standard input.

Blank lines and those whose first non-<blank> character is '#' shall be ignored.

XSI The text files **/usr/lib/cron/cron.allow** and **/usr/lib/cron/cron.deny** contain user names, one per line, of users who are, respectively, authorized or denied access to the service underlying the *crontab* utility.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *crontab*:

EDITOR Determine the editor to be invoked when the **–e** option is specified. The default editor shall be *vi*.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in

arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If the **–l** option is specified, the crontab entry shall be written to the standard output.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
The user's crontab entry is not submitted, removed, edited, or listed.

APPLICATION USAGE
The format of the *crontab* entry shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

The default settings of the *HOME*, *LOGNAME*, *PATH*, and *SHELL* variables that are given to the scheduled job are not affected by the settings of those variables when *crontab* is run; as stated, they are defaults. The text about ''invoked as specified by this volume of IEEE Std. 1003.1-200x'' means that the implementation may provide extensions that allow these variables to be affected at runtime, but that the user has to take explicit action in order to access the extension, such as give a new option flag or modify the format of the crontab entry.

A typical user error is to type only *crontab*; this causes the system to wait for the new crontab entry on standard input. If end-of-file is typed (generally <control>-D), the crontab entry is replaced by an empty file. In this case, the user should type the interrupt character, which prevents the crontab entry from being replaced.

EXAMPLES

1. Clean up **core** files every weekday morning at 3:15 am:

```
15 3 * * 1-5 find $HOME –name core 2>/dev/null | xargs rm –f
```

2. Mail a birthday greeting:

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

3. As an example of specifying the two types of days:

```
0 0 1,15 * 1
```

would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to '*'; for example:

```
0 0 * * 1
```

would run a command only on Mondays.

RATIONALE

All references to a *cron* daemon and to *cron files* have been omitted. Although historical implementations have used this arrangement, there is no reason to limit future implementations.

This description of *crontab* is designed to support only users with normal privileges. The format of the input is based on the System V *crontab*; however, there is no requirement here that the actual system database used by the *cron* daemon (or a similar mechanism) use this format internally. For example, systems derived from BSD are likely to have an additional field appended that indicates the user identity to be used when the job is submitted.

The **–e** option was adopted from the SVID as a user convenience, although it does not exist in all historical implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

10686 **NAME**

10687 csplit — split files based on context

10688 **SYNOPSIS**

10689 UP `csplit [-ks][-f prefix][-n number] file arg1 ...argn`

10690

10691 **DESCRIPTION**

10692 The *csplit* utility shall read the file named by the *file* operand, write all or part of that file into
10693 other files as directed by the *arg* operands, and write the sizes of the files.

10694 **OPTIONS**

10695 The *csplit* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
10696 12.2, Utility Syntax Guidelines.

10697 The following options shall be supported:

10698 **-f** *prefix* Name the created files *prefix***00**, *prefix***01**, ..., *prefix*n. The default is **xx00** ... **xx***n*. If
10699 the *prefix* argument would create a file name exceeding {NAME_MAX} bytes, an
10700 error shall result, *csplit* shall exit with a diagnostic message and no files shall be
10701 created.

10702 **-k** Leave previously created files intact. By default, *csplit* shall remove created files if
10703 an error occurs.

10704 **-n** *number* Use *number* decimal digits to form file names for the file pieces. The default shall be
10705 2.

10706 **-s** Suppress the output of file size messages.

10707 **OPERANDS**

10708 The following operands shall be supported:

10709 *file* The path name of a text file to be split. If *file* is '-', the standard input shall be
10710 used.

10711 The operands *arg1* ... *argn* can be a combination of the following:

10712 /*rexp*/**[***offset***]**

10713 A file shall be created using the content of the lines from the current line up to, but
10714 not including, the line that results from the evaluation of the regular expression
10715 with *offset*, if any, applied. The regular expression *rexp* shall follow the rules for
10716 basic regular expressions described in the Base Definitions volume of
10717 IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions. The application shall
10718 use the sequence "\/" to specify a slash character within the *rexp*. The optional
10719 offset shall be a positive or negative integer value representing a number of lines.
10720 A positive integer value can be preceded by '+'. If the selection of lines from an
10721 *offset* expression of this type would create a file with zero lines, or one with greater
10722 than the number of lines left in the input file, the results are unspecified. After the
10723 section is created, the current line shall be set to the line that results from the
10724 evaluation of the regular expression with any offset applied. If the current line is
10725 the first line in the file and a regular expression operation has not yet been
10726 performed, the pattern match of *rexp* shall be applied from the current line to the
10727 end of the file. Otherwise, the pattern match of *rexp* shall be applied from the line
10728 following the current line to the end of the file.

10729 %*rexp*%**[***offset***]**

10730 Equivalent to /*rexp*/**[***offset***]**, except that no file shall be created for the selected
10731 section of the input file. The application shall use the sequence "\%" to specify a

10732 percent-sign character within the *rexp*.

10733 *line_no* Create a file from the current line up to (but not including) the line number *line_no*.
10734 Lines in the file shall be numbered starting at one. The current line becomes
10735 *line_no*.

10736 {*num*} Repeat operand. This operand can follow any of the operands described
10737 previously. If it follows a *rexp* type operand, that operand shall be applied *num*
10738 more times. If it follows a *line_no* operand, the file shall be split every *line_no* lines,
10739 *num* times, from that point.

10740 An error shall be reported if an operand does not reference a line between the current position
10741 and the end of the file.

10742 **STDIN**

10743 See the INPUT FILES section.

10744 **INPUT FILES**

10745 The input file shall be a text file.

10746 **ENVIRONMENT VARIABLES**

10747 The following environment variables shall affect the execution of *csplit*:

10748 *LANG* Provide a default value for the internationalization variables that are unset or null.
10749 If *LANG* is unset or null, the corresponding value from the implementation-
10750 defined default locale shall be used. If any of the internationalization variables
10751 contains an invalid setting, the utility shall behave as if none of the variables had
10752 been defined.

10753 *LC_ALL* If set to a non-empty string value, override the values of all the other
10754 internationalization variables.

10755 *LC_COLLATE*
10756 Determine the locale for the behavior of ranges, equivalence classes, and multi-
10757 character collating elements within regular expressions.

10758 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
10759 characters (for example, single-byte as opposed to multi-byte characters in
10760 arguments and input files) and the behavior of character classes within regular
10761 expressions.

10762 *LC_MESSAGES*
10763 Determine the locale that should be used to affect the format and contents of
10764 diagnostic messages written to standard error.

10765 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

10766 **ASYNCHRONOUS EVENTS**

10767 If the **–k** option is specified, created files shall be retained. Otherwise, the default action occurs.

10768 **STDOUT**

10769 Unless the **–s** option is used, the standard output shall consist of one line per file created, with a
10770 format as follows:

10771 `"%d\n", <file size in bytes>`

STDERR

Used only for diagnostic messages.

OUTPUT FILES

The output files shall contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

By default, created files shall be removed if an error occurs. When the **–k** option is specified, created files shall not be removed if an error occurs.

APPLICATION USAGE

None.

EXAMPLES

1. This example creates four files, **cobol00** ... **cobol03**:

   ```
   csplit –f cobol file '/procedure division/' /par5./ /par16./
   ```

   After editing the split files, they can be recombined as follows:

   ```
   cat cobol0[0–3] > file
   ```

   Note that this example overwrites the original file.

2. This example would split the file after the first 99 lines, and every 100 lines thereafter, up to 9 999 lines; this is because lines in the file are numbered from 1 rather than zero, for historical reasons:

   ```
   csplit –k file  100  {99}
   ```

3. Assuming that **prog.c** follows the C-language coding convention of ending routines with a `'}'` at the beginning of the line, this example creates a file containing each separate C routine (up to 21) in **prog.c**:

   ```
   csplit –k prog.c '%main(%'  '/^}/+1' {20}
   ```

RATIONALE

The **–n** option was added to extend the range of file names that could be handled.

Consideration was given to adding a **–a** flag to use the alphabetic file name generation used by the historical *split* utility, but the functionality added by the **–n** option was deemed to make alphabetic naming unnecessary.

FUTURE DIRECTIONS

None.

The description of regular expression operands is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

ctags — create a tags file (**DEVELOPMENT**, **FORTRAN**)

SYNOPSIS

UP

```
ctags [–a][–f tagsfile] pathname ...
ctags –x pathname ...
```

DESCRIPTION

The *ctags* utility shall be provided on systems that support the User Portability Utilities option, the Software Development Utilities option, and either or both of the C-Language Development Utilities option and FORTRAN Development Utilities option. On other systems, it is optional.

The *ctags* utility shall write a *tags* file or an index of objects from C-language or FORTRAN source files specified by the *pathname* operands. The tags file shall list the locators of language-specific objects within the source files. A locator consists of a name, path name, and either a search pattern or a line number that can be used in searching for the object definition. The objects that shall be recognized are specified in the EXTENDED DESCRIPTION section.

OPTIONS

The *ctags* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–a Append to tags file.

–f *tagsfile* Write the object locator lists into *tagsfile* instead of the default file named **tags** in the current directory.

–x Produce a list of object names, the line number, and file name in which each is defined, as well as the text of that line, and write this to the standard output. A **tags** file shall not be created when **–x** is specified.

OPERANDS

The following *pathname* operands are supported:

*file***.c** Files with basenames ending with the **.c** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.h** Files with basenames ending with the **.h** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.f** Files with basenames ending with the **.f** suffix shall be treated as FORTRAN-language source code. Such files that are not valid input to *fort77* produce unspecified results.

The handling of other files is implementation-defined.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files containing source code in the language indicated by the operand file name suffixes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ctags*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the order in which output is sorted for the **–x** option. The POSIX locale determines the order in which the tags file is written.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). When processing C-language source code, if the locale is not compatible with the C locale described by the ISO C standard, the results are unspecified.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The list of object name information produced by the **–x** option shall be written to standard output in the following format:

```
"%s %d %s %s", <object-name>, <line-number>, <filename>,
    <text>
```

where <*text*> is the text of line <*line-number*> of file <*filename*>.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

When the **–x** option is not specified, the format of the output file shall be:

```
"%s\t%s\t/%s/\n", <identifier>, <filename>, <pattern>
```

where <*pattern*> is a search pattern that could be used by an editor to find the defining instance of <*identifier*> in <*filename*> (where *defining instance* is indicated by the declarations listed in the EXTENDED DESCRIPTION).

An optional circumflex (`'^'`) can be added as a prefix to <*pattern*>, and an optional dollar sign can be appended to <*pattern*> to indicate that the pattern is anchored to the beginning (end) of a line of text. Any slash or backslash characters in <*pattern*> shall be preceded by a backslash character. The anchoring circumflex, dollar sign, and escaping backslash characters shall not be considered part of the search pattern. All other characters in the search pattern shall be considered literal characters.

An alternative format is:

`"%s\t%s\t?%s?\n", <identifier>, <filename>, <pattern>`

which is identical to the first format except that slashes in <*pattern*> shall not be preceded by escaping backslash characters, and question mark characters in <*pattern*> shall be preceded by backslash characters.

A second alternative format is:

`"%s\t%s\t%d\n", <identifier>, <filename>, <lineno>`

where <*lineno*> is a decimal line number that could be used by an editor to find <*identifier*> in <*filename*>.

Neither alternative format shall be produced by *ctags* when it is used as described by IEEE Std. 1003.1-200x, but the standard utilities that process tags files shall be able to process those formats as well as the first format.

In any of these formats, the file shall be sorted by identifier, based on the collation sequence in the POSIX locale.

EXTENDED DESCRIPTION

If the operand identifies C-language source, the *ctags* utility shall attempt to produce an output line for each of the following objects:

- Function definitions
- Type definitions
- Macros with arguments

It may also produce output for any of the following objects:

- Function prototypes
- Structures
- Unions
- Global variable definitions
- Enumeration types
- Macros without arguments
- **#define** statements
- **#line** statements

Any **#if** and **#ifdef** statements shall produce no output. The tag **main** is treated specially in C programs. The tag formed shall be created by prefixing **M** to the name of the file, with the trailing **.c**, and leading path name components (if any) removed.

On systems that do not support the C-Language Development Utilities option, *ctags* produces undefined results for C-language source code files.

If the operand identifies FORTRAN source, the *ctags* utility shall produce an output line for each function definition. It may also produce output for any of the following objects:

- Subroutine definitions
- COMMON statements

- PARAMETER statements
- DATA and BLOCK DATA statements
- Statement numbers

On systems that do not support the FORTRAN Development Utilities option, *ctags* produces unspecified results for FORTRAN source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

It is implementation-defined what other objects (including duplicate identifiers) produce output.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The output with **–x** is meant to be a simple index that can be written out as an off-line readable function index. If the input files to *ctags* (such as **.c** files) were not created using the same locales as those in effect when *ctags* **–x** is run, results might not be as expected.

The description of C-language processing says ''attempts to'' because the C language can be greatly confused, especially through the use of **#define**s, and this utility would be of no use if the real C preprocessor were run to identify them. The output from *ctags* may be fooled and incorrect for various constructs.

EXAMPLES

None.

RATIONALE

The option list was significantly reduced from that provided by historical implementations. The **–F** option was omitted as redundant, since it is the default. The **–B** option was omitted as being of very limited usefulness. The **–t** option was omitted since the recognition of typedefs is now required for C source files. The **–u** option was omitted because the update function was judged to be not only inefficient, but also rarely needed.

An early proposal included a **–w** option to suppress warning diagnostics. Since the types of such diagnostics could not be described, the option was omitted as being not useful.

The text for *LC_CTYPE* about compatibility with the C locale acknowledges that the ISO C standard imposes requirements on the locale used to process C source. This could easily be a superset of that known as ''the C locale'' by way of implementation extensions, or one of a few alternative locales for systems supporting different codesets. No statement is made for FORTRAN because the ANSI X3.9-1978 standard (FORTRAN 77) does not (yet) define a similar locale concept. However, a general rule in this volume of IEEE Std. 1003.1-200x is that any time that locales do not match (preparing a file for one locale and processing it in another), the results are suspect.

The collation sequence of the tags file is not affected by *LC_COLLATE* because it is typically not used by human readers, but only by programs such as *vi* to locate the tag within the source files. Using the POSIX locale eliminates some of the problems of coordinating locales between the *ctags* file creator and the *vi* file reader.

Historically, the tags file has been used only by *ex* and *vi*. However, the format of the tags file has been published to encourage other programs to use the tags in new ways. The format allows either patrerns or line numbers to find the identifiers because the historical *vi* recognizes either. The *ctags* utility does not produce the format using line numbers because it is not useful following any source file changes that add or delete lines. The documented search patterns match historical practice. It should be noted that literal leading circumflex or trailing dollar-sign characters in the search pattern will only behave correctly if anchored to the beginning of the line or end of the line by an additional circumflex or dollar-sign character.

Historical implementations also understand the objects used by the languages Pascal and sometimes LISP, and they understand the C source output by *lex* and *yacc*. The *ctags* utility is not required to accommodate these languages, although implementors are encouraged to do so.

The following historical option was not specified, as *vgrind* is not included in this volume of IEEE Std. 1003.1-200x:

–v If the **–v** flag is given, an index of the form expected by *vgrind* is produced on the standard output. This listing contains the function name, file name, and page number (assuming 64-line pages). Since the output is sorted into lexicographic order, it may be desired to run the output through *sort* **–f**. Sample use:

```
ctags –v files | sort –f > index vgrind –x index
```

The special treatment of the tag **main** makes the use of *ctags* practical in directories with more than one program.

FUTURE DIRECTIONS

None.

SEE ALSO

c99, *fort77*, *vi*

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The OUTPUT FILES section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

IEEE PASC Interpretation 1003.2 #168 is applied, changing ‘‘create’’ to ‘‘write’’ in the DESCRIPTION.

11020 **NAME**

11021 cut — cut out selected fields of each line of a file

11022 **SYNOPSIS**

11023 `cut –b` *list* `[–n] [`*file* `...]`

11024 `cut –c` *list* `[`*file* `...]`

11025 `cut –f` *list* `[–d` *delim*`][–s][`*file* `...]`

11026 **DESCRIPTION**

11027 The *cut* utility shall cut out bytes (**–b** option), characters (**–c** option) or character-delimited fields
11028 (**–f** option) from each line in one or more files, concatenate them, and write them to standard
11029 output.

11030 **OPTIONS**

11031 The *cut* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
11032 12.2, Utility Syntax Guidelines.

11033 The application shall ensure that the option-argument *list* (see options **–b**, **–c**, and **–f** below) is a
11034 comma-separated list or <blank> character-separated list of positive numbers and ranges.
11035 Ranges can be in three forms. The first is two positive numbers separated by a hyphen
11036 (*low–high*), which represents all fields from the first number to the second number. The second is
11037 a positive number preceded by a hyphen (*–high*), which represents all fields from field number 1
11038 to that number. The third is a positive number followed by a hyphen (*low–*), which represents
11039 that number to the last field, inclusive. The elements in *list* can be repeated, can overlap, and can
11040 be specified in any order, but the bytes, characters, or fields selected shall be written in the order
11041 of the input data. If an element appears in the selection list more than once, it shall be written
11042 exactly once.

11043 The following options shall be supported:

11044 **–b** *list* Cut based on a *list* of bytes. Each selected byte shall be output unless the **–n** option
11045 is also specified. It shall not be an error to select bytes not present in the input line.

11046 **–c** *list* Cut based on a *list* of characters. Each selected character shall be output. It shall
11047 not be an error to select characters not present in the input line.

11048 **–d** *delim* Set the field delimiter to the character *delim*. The default is the <tab> character.

11049 **–f** *list* Cut based on a *list* of fields, assumed to be separated in the file by a delimiter
11050 character (see **–d**). Each selected field shall be output. Output fields shall be
11051 separated by a single occurrence of the field delimiter character. Lines with no field
11052 delimiters shall be passed through intact, unless **–s** is specified. It shall not be an
11053 error to select fields not present in the input line.

11054 **–n** Do not split characters. When specified with the **–b** option, each element in *list* of
11055 the form *low–high* (hyphen-separated numbers) shall be modified as follows:

11056 • If the byte selected by *low* is not the first byte of a character, *low* shall be
11057 decremented to select the first byte of the character originally selected by *low*.
11058 If the byte selected by *high* is not the last byte of a character, *high* shall be
11059 decremented to select the last byte of the character prior to the character
11060 originally selected by *high*, or zero if there is no prior character. If the resulting
11061 range element has *high* equal to zero or *low* greater than *high*, the list element
11062 shall be dropped from *list* for that input line without causing an error.

11063 Each element in *list* of the form *low–* shall be treated as above with *high* set to the
11064 number of bytes in the current line, not including the terminating <newline>

character. Each element in *list* of the form –*high* shall be treated as above with *low* set to 1. Each element in *list* of the form *num* (a single number) shall be treated as above with *low* set to *num* and *high* set to *num*.

–**s** Suppress lines with no delimiter characters, when used with the –**f** option. Unless specified, lines with no delimiters shall be passed through untouched.

OPERANDS

The following operand shall be supported:

file A path name of an input file. If no *file* operands are specified, or if a *file* operand is `'–'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cut*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *cut* utility output shall be a concatenation of the selected bytes, characters, or fields (one of the following):

`"%s\n", <`*`concatenation of bytes`*`>`

`"%s\n", <`*`concatenation of characters`*`>`

`"%s\n", <`*`concatenation of fields and field delimiters`*`>`

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Earlier versions of the *cut* utility worked in an environment where bytes and characters were considered equivalent (modulo <backspace> and <tab> character processing in some implementations). In the extended world of multi-byte characters, the new **–b** option has been added. The **–n** option (used with **–b**) allows it to be used to act on bytes rounded to character boundaries. The algorithm specified for **–n** guarantees that:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

ends up with all the characters in **file** appearing exactly once in **file1** or **file2**. (There is, however, a <newline> character in both **file1** and **file2** for each <newline> character in **file**.)

EXAMPLES

Examples of the option qualifier list:

1,4,7 Select the first, fourth, and seventh bytes, characters, or fields and field delimiters.

1–3,8 Equivalent to 1,2,3,8.

–5,10 Equivalent to 1,2,3,4,5,10.

3– Equivalent to third to last, inclusive.

The *low–high* forms are not always equivalent when used with **–b** and **–n** and multi-byte characters; see the description of **–n**.

The following command:

```
cut –d : –f 1,6 /etc/passwd
```

reads the System V password file (user database) and produces lines of the form:

<user ID>:<home directory>

Most utilities in this volume of IEEE Std. 1003.1-200x work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if **file** contains long lines:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline> character) and **file2** that contains the remainder of the data from **file**. (Note that **file2** is not a text file if there are lines in **file** that are longer than 500 + {LINE_MAX} bytes.) The original file can be recreated from **file1** and **file2** using the command:

```
paste –d "\0" file1 file2 > file
```

RATIONALE

Some historical implementations do not count <backspace> characters in determining character counts with the **–c** option. This may be useful for using *cut* for processing *nroff* output. It was deliberately decided not to have the **–c** option treat either <backspace> or <tab> characters in any special fashion. The *fold* utility does treat these characters specially.

Unlike other utilities, some historical implementations of *cut* exit after not finding an input file, rather than continuing to process the remaining *file* operands. This behavior is prohibited by this volume of IEEE Std. 1003.1-200x, where only the exit status is affected by this problem.

The behavior of *cut* when provided with either mutually-exclusive options or options that do not work logically together has been deliberately left unspecified in favor of global wording in Section 1.11 (on page 2224).

The OPTIONS section was changed in response to P1003.2-N149. The change represents historical practice on all known systems. The original standard was ambiguous on the nature of the output.

The *list* option-arguments are historically used to select the portions of the line to be written, but do not affect the order of the data. For example:

```
echo abcdefghi | cut –c6,2,4–7,1
```

yields `"abdefg"`.

A proposal to enhance *cut* with the following option:

–o Preserve the selected field order. When this option is specified, each byte, character, or field (or ranges of such) shall be written in the order specified by the *list* option-argument, even if this requires multiple outputs of the same bytes, characters, or fields.

was rejected because this type of enhancement is outside the scope of the IEEE P1003.2b draft standard.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The OPTIONS section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

cxref — generate a C-language program cross-reference table (**DEVELOPMENT**)

SYNOPSIS

XSI
```
cxref [–cs][–o file][–w num] [–D name[=def]]...[–I dir]...
    [–U name]... file ...
```

DESCRIPTION

The *cxref* utility shall analyze a collection of C-language *file*s and attempt to build a cross-reference table. Information from **#define** lines is included in the symbol table. A sorted listing shall be written to standard output of all symbols (auto, static, and global) in each *file* separately, or with the **–c** option, in combination. Each symbol contains an asterisk before the declaring reference.

OPTIONS

The *cxref* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the **–D**, **–I**, and **–U** options (which are identical to their interpretation by *c99*) is significant. The following options shall be supported:

–c Write a combined cross-reference of all input files.

–w *num* Format output no wider than *num* (decimal) columns. This option defaults to 80 if *num* is not specified or is less than 51.

–o *file* Direct output to named *file*.

–s Operate silently; do not print input file names.

OPERANDS

The following operand shall be supported:

file A path name of a C-language source file.

STDIN

Not used.

INPUT FILES

The input files are C-language source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cxref*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used for the cross-reference listing, unless the **−o** option is used to select a different output file.

The format of standard output is unspecified, except that the following information shall be included:

- If the **−c** option is not specified, each portion of the listing starts with the name of the input file on a separate line.
- The name line is followed by a sorted list of symbols, each with its associated location path name, the name of the function in which it appears (if it is not a function name itself), and line number references.
- Each line number may be preceded by an asterisk (`'*'`) flag, meaning that this is the declaring reference. Other single-character flags, with implementation-defined meanings, may be included.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

The output file named by the **−o** option shall be used instead of standard output.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Utility Syntax Guidelines support mandated.

Internationalized environment variable support mandated.

Issue 5

In the SYNOPSIS, [**–U** *dir*]*is*changed*to*[**–U** *name*].

Issue 6

The APPLICATION USAGE section is added.

11276 **NAME**

11277 date — write the date and time

11278 **SYNOPSIS**

11279 `date [–u] [+`*format*`]`

11280 XSI `date [–u] `*mmddhhmm*`[[`*cc*`]`*yy*`]`

11281

11282 **DESCRIPTION**

11283 XSI The *date* utility shall write the date and time to standard output or attempt to set the system date
11284 and time. By default, the current date and time shall be written. If an operand beginning with
11285 `'+'` is specified, the output format of *date* shall be controlled by the field descriptors and other
11286 text in the operand.

11287 **OPTIONS**

11288 The *date* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section |
11289 12.2, Utility Syntax Guidelines. |

11290 The following option shall be supported:

11291 **–u** Perform operations as if the *TZ* environment variable was set to the string `"UTC0"`,
11292 or its equivalent historical value of `"GMT0"`. Otherwise, *date* shall use the
11293 timezone indicated by the *TZ* environment variable or the system default if that
11294 variable is not set.

11295 **OPERANDS**

11296 The following operands shall be supported:

11297 *+format* When the format is specified, each field descriptor shall be replaced in the
11298 standard output by its corresponding value. All other characters shall be copied to
11299 the output without change. The output always shall be terminated with a
11300 <newline> character. |

11301 **Field Descriptors**

11302 %*a* Locale's abbreviated weekday name.

11303 %*A* Locale's full weekday name.

11304 %*b* Locale's abbreviated month name.

11305 %*B* Locale's full month name.

11306 %*c* Locale's appropriate date and time representation.

11307 %*C* Century (a year divided by 100 and truncated to an integer) as a decimal
11308 number [00-99].

11309 %*d* Day of the month as a decimal number [01-31].

11310 %*D* Date in the format *mm*/*dd*/*yy*.

11311 %*e* Day of the month as a decimal number [1-31] in a two-digit field with
11312 leading space character fill.

11313 %*h* A synonym for %*b*.

11314 %*H* Hour (24-hour clock) as a decimal number [00-23].

11315 %*I* Hour (12-hour clock) as a decimal number [01-12].

11316	%*j*	Day of the year as a decimal number [001-366].
11317	%*m*	Month as a decimal number [01-12].
11318	%*M*	Minute as a decimal number [00-59].
11319	%*n*	A <newline> character.
11320	%*p*	Locale's equivalent of either AM or PM.
11321 11322	%*r*	12-hour clock time [01-12] using the AM/PM notation; in the POSIX locale, this is equivalent to %*I*:%*M*:%*S*% *p*.
11323	%*S*	Seconds as a decimal number [00-61].
11324	%*t*	A <tab> character.
11325	%*T*	24-hour clock time [00-23] in the format *HH*:*MM*:*SS*.
11326	%*u*	Weekday as a decimal number [1 (Monday)-7].
11327 11328 11329	%*U*	Week of the year (Sunday as the first day of the week) as a decimal number [00-53]. All days in a new year preceding the first Sunday shall be considered to be in week 0.
11330 11331 11332 11333	%*V*	Week of the year (Monday as the first day of the week) as a decimal number [01-53]. If the week containing January 1 has four or more days in the new year, then it shall be considered week 1; otherwise, it shall be the last week of the previous year, and the next week shall be week 1.
11334	%*w*	Weekday as a decimal number [0 (Sunday)-6].
11335 11336 11337	%*W*	Week of the year (Monday as the first day of the week) as a decimal number [00-53]. All days in a new year preceding the first Monday shall be considered to be in week 0.
11338	%*x*	Locale's appropriate date representation.
11339	%*X*	Locale's appropriate time representation.
11340	%*y*	Year within century [00-99].
11341	%*Y*	Year with century as a decimal number.
11342	%*Z*	Timezone name, or no characters if no timezone is determinable.
11343	%%	A percent sign character.

11344 See the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3.5, LC_TIME
11345 for the field descriptor values in the POSIX locale.

11346 **Modified Field Descriptors**

11347 Some field descriptors can be modified by the *E* and *O* modifier characters to
11348 indicate a different format or specification as specified in the *LC_TIME* locale
11349 description (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3.5,
11350 LC_TIME). If the corresponding keyword (see **era**, **era_year**, **era_d_fmt**, and
11351 **alt_digits** in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3.5,
11352 LC_TIME) is not specified or not supported for the current locale, the unmodified
11353 field descriptor value shall be used.

11354	%*Ec*	Locale's alternative appropriate date and time representation.

	%*EC*	The name of the base year (period) in the locale's alternative representation.
	%*Ex*	Locale's alternative date representation.
	%*EX*	Locale's alternative time representation.
	%*Ey*	Offset from %*EC* (year only) in the locale's alternative representation.
	%*EY*	Full alternative year representation.
	%*Od*	Day of month using the locale's alternative numeric symbols.
	%*Oe*	Day of month using the locale's alternative numeric symbols.
	%*OH*	Hour (24-hour clock) using the locale's alternative numeric symbols.
	%*OI*	Hour (12-hour clock) using the locale's alternative numeric symbols.
	%*Om*	Month using the locale's alternative numeric symbols.
	%*OM*	Minutes using the locale's alternative numeric symbols.
	%*OS*	Seconds using the locale's alternative numeric symbols.
	%*Ou*	Weekday as a number in the locale's alternative representation (Monday = 1).
	%*OU*	Week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.
	%*OV*	Week number of the year (Monday as the first day of the week, rules corresponding to %*V*), using the locale's alternative numeric symbols.
	%*Ow*	Weekday as a number in the locale's alternative representation (Sunday = 0).
	%*OW*	Week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
	%*Oy*	Year (offset from %*C*) in alternative representation.

XSI *mmddhhmm***[[***cc***]***yy* **]**

Attempt to set the system date and time from the value given in the operand. This is only possible if the user has appropriate privileges and the system permits the setting of the system date and time. The first *mm* is the month (number); *dd* is the day (number); *hh* is the hour (number, 24-hour system); the second *mm* is the minute (number); *cc* is the century and is the first two digits of the year (this is optional); *yy* is the last two digits of the year and is optional. If century is not specified, then values in the range [69-99] shall refer to years 1969 to 1999 inclusive, and values in the range [00-68] shall refer to years 2000 to 2068 inclusive.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *date*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-

defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *date*.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone in which the time and date are written, unless the **–u** option is specified. If the *TZ* variable is not set and the **–u** is not specified, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When no formatting operand is specified, the output in the POSIX locale shall be equivalent to specifying:

```
date "+%a %b %e %H:%M:%S %Z %Y"
```

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The date was written successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Field descriptors are of unspecified format when not in the POSIX locale. Some of them can contain <newline> characters in some locales, so it may be difficult to use the format shown in standard output for parsing the output of *date* in those locales.

The range of values for %*S* extends from 0 to 61 seconds to accommodate the occasional leap second or double leap second.

Although certain of the field descriptors in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a

sentence.

The date string formatting capabilities are intended for use in Gregorian-style calendars, possibly with a different starting year (or years). The %*x* and %*c* field descriptors, however, are intended for local representation; these may be based on a different, non-Gregorian calendar.

The %*C* field descriptor was introduced to allow a fallback for the %*EC* (alternative year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. A century is not calculated as an ordinal number; IEEE Std. 1003.1-200x was published in century 20, not the twenty-first. Both the %*Ey* and %*y* can then be viewed as the offset from %*EC* and %*C*, respectively.

The *E* and *O* modifiers modify the traditional field descriptors, so that they can always be used, even if the implementation (or the current locale) does not support the modifier.

The *E* modifier supports alternative date formats, such as the Japanese Emperor's Era, as long as these are based on the Gregorian calendar system. Extending the *E* modifiers to other date elements may provide an implementation-defined extension capable of supporting other calendar systems, especially in combination with the *O* modifier.

The *O* modifier supports time and date formats using the locale's alternative numerical symbols, such as Kanji or Hindi digits or ordinal number representation.

Non-European locales, whether they use Latin digits in computational items or not, often have local forms of the digits for use in date formats. This is not totally unknown even in Europe; a variant of dates uses Roman numerals for the months: the third day of September 1991 would be written as 3.IX.1991. In Japan, Kanji digits are regularly used for dates; in Arabic-speaking countries, Hindi digits are used. The %*d*, %*e*, %*H*, %*I*, %*m*, %*S*, %*U*, %*w*, %*W*, and %*y* field descriptors always return the date and time field in Latin digits (that is, 0 to 9). The %*O* modifier was introduced to support the use for display purposes of non-Latin digits. In the *LC_TIME* category in *localedef*, the optional **alt_digits** keyword is intended for this purpose. As an example, assume the following (partial) *localedef* source:

```
alt_digits  "";"I";"II";"III";"IV";"V";"VI";"VII";"VIII" \
            "IX";"X";"XI";"XII"
d_fmt       "%e.%Om.%Y"
```

With the above date, the command:

```
date "+%x"
```

would yield 3.IX.1991. With the same **d_fmt**, but without the **alt_digits**, the command would yield 3.9.1991.

EXAMPLES

1. The following are input/output examples of *date* used at arbitrary times in the POSIX locale:

```
$ date
Tue Jun 26 09:58:10 PDT 1990

$ date "+DATE: %m/%d/%y%nTIME: %H:%M:%S"
DATE: 11/02/91
TIME: 13:36:16

$ date "+TIME: %r"
TIME: 01:36:32 PM
```

2. Examples for Denmark, where the default date and time format is %*a* %*d* %*b* %*Y* %*T* %*Z*:

```
$ LANG=da_DK.iso_8859–1 date
ons 02 okt 1991 15:03:32 CET

$ LANG=da_DK.iso_8859–1 date "+DATO: %A den %e. %B %Y%nKLOKKEN: %H:%M:%S
DATO: onsdag den 2. oktober 1991
KLOKKEN: 15:03:56
```

3. Examples for Germany, where the default date and time format is %*a* %*d*.%*h*.%*Y*, %*T* %*Z*:

```
$ LANG=De_DE.88591 date
Mi 02.Okt.1991, 15:01:21 MEZ

$ LANG=De_DE.88591 date "+DATUM: %A, %d. %B %Y%nZEIT: %H:%M:%S"
DATUM: Mittwoch, 02. Oktober 1991
ZEIT: 15:02:02
```

4. Examples for France, where the default date and time format is %*a* %*d* %*h* %*Y* %*Z* %T:

```
$ LANG=Fr_FR.88591 date
Mer 02 oct 1991 MET 15:03:32

$ LANG=Fr_FR.88591 date "+JOUR: %A %d %B %Y%nHEURE: %H:%M:%S"
JOUR: Mercredi 02 octobre 1991
HEURE: 15:03:56
```

RATIONALE

Some of the new options for formatting are from the ISO C standard. The **–u** option was introduced to allow portable access to Coordinated Universal Time (UTC). The string `"GMT0"` is allowed as an equivalent *TZ* value to be compatible with all of the systems using the BSD implementation, where this option originated.

The %*e* format field descriptor (adopted from System V) was added because the ISO C standard descriptors did not provide any way to produce the historical default *date* output during the first nine days of any month.

There are two varieties of day and week numbering supported (in addition to any others created with the locale-dependent %*E* and %*O* modifier characters):

- The historical variety in which Sunday is the first day of the week and the weekdays preceding the first Sunday of the year are considered week 0. These are represented by %*w* and %*U*. A variant of this is %*W*, using Monday as the first day of the week, but still referring to week 0. This view of the calendar was retained because so many historical applications depend on it and the ISO C standard *strftime*() function, on which many *date* implementations are based, was defined in this way.
- The international standard, based on the ISO 8601:1988 standard where Monday is the first weekday and the algorithm for the first week number is more complex: If the week (Monday to Sunday) containing January 1 has four or more days in the new year, then it is week 1; otherwise, it is week 53 of the previous year, and the next week is week 1. These are represented by the new field descriptors %*u* and %*V*, added as a result of international comments.

The %*C* field descriptor was introduced to allow a fallback for the %*EC* (alternate year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. A century is not calculated as an ordinal number. The original version of this volume of IEEE Std. 1003.1-200x was approved in century 19, not the twentieth. Both the %*Ey* and %*y* can then be viewed as the offset from %*EC* and %*C*, respectively.

FUTURE DIRECTIONS

None.

SEE ALSO

The System Interfaces volume of IEEE Std. 1003.1-200x, *ctime*( ), *printf*( )

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

Changes are made for Year 2000 alignment.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The setting of system date and time is described, including how to interpret two-digit year values if a century is not given.
- The %*EX* modified field descriptor is added.

The Open Group corrigenda item U048 / 2 has been applied, correcting the examples.

NAME

dd — convert and copy a file

SYNOPSIS

```
dd [operand ...]
```

DESCRIPTION

The *dd* utility shall copy the specified input file to the specified output file with possible conversions using specific input and output block sizes. It shall read the input one block at a time, using the specified input block size; it shall then process the block of data actually returned, which could be smaller than the requested block size. It shall apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size. If the **bs**=*expr* operand is specified and no conversions other than **sync**, **noerror**, or **notrunc** are requested, the data returned from each input block shall be written as a separate output block; if the read returns less than a full block and the **sync** conversion is not specified, the resulting output block shall be the same size as the input block. If the **bs**=*expr* operand is not specified, or a conversion other than **sync**, **noerror**, or **notrunc** is requested, the input shall be processed and collected into full-sized output blocks until the end of the input is reached.

The processing order shall be as follows:

1. An input block is read.
2. If the input block is shorter than the specified input block size and the **sync** conversion is specified, null bytes shall be appended to the input data up to the specified size. (If either **block** or **unblock** is also specified, <space> characters shall be appended instead of null bytes.) The remaining conversions and output shall include the pad characters as if they had been read from the input.
3. If the **bs**=*expr* operand is specified and no conversion other than **sync** or **noerror** is requested, the resulting data shall be written to the output as a single block, and the remaining steps are omitted.
4. If the **swab** conversion is specified, each pair of input data bytes shall be swapped. If there is an odd number of bytes in the input block, the last byte in the input record shall not be swapped.
5. Any remaining conversions (**block**, **unblock**, **lcase**, and **ucase**) shall be performed. These conversions shall operate on the input data independently of the input blocking; an input or output fixed-length record may span block boundaries.
6. The data resulting from input or conversion or both shall be aggregated into output blocks of the specified size. After the end of input is reached, any remaining output shall be written as a block without padding if **conv**=**sync** is not specified; thus, the final output block may be shorter than the output block size.

OPTIONS

None.

OPERANDS

All of the operands shall be processed before any input is read. The following operands shall be supported:

if=*file* Specify the input path name; the default is standard input.

of=*file* Specify the output path name; the default is standard output. If the **seek**=*expr* conversion is not also specified, the output file shall be truncated before the copy begins, unless **conv**=**notrunc** is specified. If **seek**=*expr* is specified, but

conv=**notrunc** is not, the effect of the copy shall be to preserve the blocks in the output file over which *dd* seeks, but no other portion of the output file shall be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file shall be shortened by the copy.)

ibs=*expr* Specify the input block size, in bytes, by *expr* (default is 512).

obs=*expr* Specify the output block size, in bytes, by *expr* (default is 512).

bs=*expr* Set both input and output block sizes to *expr* bytes, superseding **ibs**= and **obs**=. If no conversion other than **sync**, **noerror**, and **notrunc** is specified, each input block shall be copied to the output as a single block without aggregating short blocks.

cbs=*expr* Specify the conversion block size for **block** and **unblock** in bytes by *expr* (default is zero). If **cbs**= is omitted or given a value of zero, using **block** or **unblock** produces unspecified results.

XSI The application shall ensure that this operand is also specified if the **conv**= operand is specified with a value of **ascii**, **ebcdic**, or **ibm**. For a **conv**= operand with an **ascii** value, the input is handled as described for the **unblock** value, except that characters are converted to ASCII before any trailing <space> characters are deleted. For **conv**= operands with **ebcdic** or **ibm** values, the input is handled as described for the **block** value except that the characters are converted to EBCDIC or IBM EBCDIC, respectively, after any trailing <space> characters are added.

skip=*n* Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation shall read the blocks or seek past them; on non-seekable files, the blocks shall be read and the data shall be discarded.

seek=*n* Skip *n* blocks (using the specified output block size) from beginning of the output file before copying. On non-seekable files, existing blocks shall be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation shall seek to the specified offset or read the blocks as described for non-seekable files.

count=*n* Copy only *n* input blocks.

conv=*value***[**,*value* ...**]**

Where *value*s are comma-separated symbols from the following list:

XSI **ascii** Convert EBCDIC to ASCII; see Table 4-6 (on page 2518).

XSI **ebcdic** Convert ASCII to EBCDIC; see Table 4-6 (on page 2518).

XSI **ibm** Convert ASCII to a different EBCDIC set; see Table 4-7 (on page 2518).

The **ascii**, **ebcdic**, and **ibm** values are mutually-exclusive.

block Treat the input as a sequence of <newline> character-terminated or end-of-file-terminated variable-length records independent of the input block boundaries. Each record shall be converted to a record with a fixed length specified by the conversion block size. Any <newline> character shall be removed from the input line; <space> characters shall be appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size shall be truncated to the largest number of characters that fit into that size; the number of truncated lines shall be reported (see the STDERR section).

11635 The **block** and **unblock** values are mutually-exclusive.

11636 **unblock** Convert fixed-length records to variable length. Read a number of
11637 bytes equal to the conversion block size (or the number of bytes
11638 remaining in the input, if less than the conversion block size), delete
11639 all trailing <space> characters, and append a <newline> character.

11640 **lcase** Map uppercase characters specified by the *LC_CTYPE* keyword
11641 **tolower** to the corresponding lowercase character. Characters for
11642 which no mapping is specified shall not be modified by this
11643 conversion.

11644 The **lcase** and **ucase** symbols are mutually-exclusive.

11645 **ucase** Map lowercase characters specified by the *LC_CTYPE* keyword
11646 **toupper** to the corresponding uppercase character. Characters for
11647 which no mapping is specified shall not be modified by this
11648 conversion.

11649 **swab** Swap every pair of input bytes.

11650 **noerror** Do not stop processing on an input error. When an input error
11651 occurs, a diagnostic message shall be written on standard error,
11652 followed by the current input and output block counts in the same
11653 format as used at completion (see the STDERR section). If the **sync**
11654 conversion is specified, the missing input shall be replaced with null
11655 bytes and processed normally; otherwise, the input block shall be
11656 omitted from the output.

11657 **notrunc** Do not truncate the output file. Preserve blocks in the output file not
11658 explicitly written by this invocation of the *dd* utility. (See also the
11659 preceding **of**=*file* operand.)

11660 **sync** Pad every input block to the size of the **ibs**= buffer, appending null
11661 bytes. (If either **block** or **unblock** is also specified, append <space>
11662 characters, rather than null bytes.)

11663 The behavior is unspecified if operands other than **conv**= are specified more than once.

11664 For the **bs**=, **cbs**=, **ibs**=, and **obs**= operands, the application shall supply an expression
11665 specifying a size in bytes. The expression, *expr*, can be:

11666 1. A positive decimal number

11667 2. A positive decimal number followed by *k*, specifying multiplication by 1 024

11668 3. A positive decimal number followed by *b*, specifying multiplication by 512

11669 4. Two or more positive decimal numbers (with or without *k* or *b*) separated by *x*, specifying
11670 the product of the indicated values

11671 All of the operands are processed before any input is read.

11672 XSI The following two tables display the octal number character values used for the **ascii** and **ebcdic**
11673 conversions (first table) and for the **ibm** conversion (second table). In both tables, the ASCII
11674 values are the row and column headers and the EBCDIC values are found at their intersections.
11675 For example, ASCII 0012 (LF) is the second row, third column, yielding 0045 in EBCDIC. The
11676 inverted tables (for EBCDIC to ASCII conversion) are not shown, but are in one-to-one
11677 correspondence with these tables. The differences between the two tables are highlighted by
11678 small boxes drawn around five entries.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

The following 2 tables are commented out of this draft to make document handling easier (ability to print 2-up). There are no changes to them. These diagrams are available from the Austin Group web site as a separate PDF file.

Table 4-6 ASCII to EBCDIC Conversion

Table 4-7 ASCII to IBM EBCDIC Conversion

STDIN

If no **if**= operand is specified, the standard input shall be used. See the INPUT FILES section.

INPUT FILES

The input file can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *dd*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the classification of characters as uppercase or lowercase, and the mapping of characters from one case to the other.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

For SIGINT, the *dd* utility shall interrupt its current processing, write status information to standard error, and exit as though terminated by SIGINT. It shall take the standard action for all other signals; see the ASYNCHRONOUS EVENTS section in Section 1.11 (on page 2224).

STDOUT

If no **of**= operand is specified, the standard output shall be used. The nature of the output depends on the operands selected.

STDERR

On completion, *dd* shall write the number of input and output blocks to standard error. In the POSIX locale the following formats shall be used:

```
"%u+%u records in\n", <number of whole input blocks>,
    <number of partial input blocks>
"%u+%u records out\n", <number of whole output blocks>,
    <number of partial output blocks>
```

A partial input block is one for which *read*( ) returned less than the input block size. A partial output block is one that was written with fewer bytes than specified by the output block size.

In addition, when there is at least one truncated block, the number of truncated blocks shall be written to standard error. In the POSIX locale, the format shall be:

```
"%u truncated %s\n", <number of truncated blocks>, "record" (if
    <number of truncated blocks> is one) "records" (otherwise)
```

Diagnostic messages may also be written to standard error.

OUTPUT FILES

If the **of**= operand is used, the output shall be the same as described in the STDOUT section.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The input file was copied successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If an input error is detected and the **noerror** conversion has not been specified, any partial output block shall be written to the output file, a diagnostic message shall be written, and the copy operation shall be discontinued. If some other error is detected, a diagnostic message shall be written and the copy operation shall be discontinued.

APPLICATION USAGE

The input and output block size can be specified to take advantage of raw physical I/O.

There are many different versions of the EBCDIC codesets. The ASCII and EBCDIC conversions specified for the *dd* utility perform conversions for the version specified by the tables.

EXAMPLES

The following command:

```
dd if=/dev/rmt0h  of=/dev/rmt1h
```

copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

The following command:

```
dd ibs=10  skip=1
```

strips the first 10 bytes from standard input.

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file **x**:

```
dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

RATIONALE

The OPTIONS section is listed as ‘‘None’’ because there are no options recognized by historical *dd* utilities. Certainly, many of the operands could have been designed to use the Utility Syntax Guidelines, which would have resulted in the classic hyphenated option letters. In this version of this volume of IEEE Std. 1003.1-200x, *dd* retains its curious JCL-like syntax due to the large number of applications that depend on the historical implementation.

A suggested implementation technique for **conv**=**noerror**,**sync** is to zero (or <space>-fill, if **block**ing or **unblock**ing) the input buffer before each read and to write the contents of the input

buffer to the output even after an error. In this manner, any data transferred to the input buffer before the error was detected is preserved. Another point is that a failed read on a regular file or a disk generally does not increment the file offset, and *dd* must then seek past the block on which the error occurred; otherwise, the input error occurs repetitively. When the input is a magnetic tape, however, the tape normally has passed the block containing the error when the error is reported, and thus no seek is necessary.

The default **ibs**= and **obs**= sizes are specified as 512 bytes because there are historical (largely portable) scripts that assume these values. If they were left unspecified, unusual results could occur if an implementation chose an odd block size.

Historical implementations of *dd* used *creat*( ) when processing **of**=*file*. This makes the **seek**= operand unusable except on special files. The **conv**=**notrunc** feature was added because more recent BSD-based implementations use *open*( ) (without O_TRUNC) instead of *creat*( ), but they fail to delete output file contents after the data copied.

The *w* multiplier (historically meaning *word*), is used in System V to mean 2 and in 4.2 BSD to mean 4. Since *word* is inherently non-portable, its use is not supported by this volume of IEEE Std. 1003.1-200x.

Standard EBCDIC does not have the characters '[' and ']'. The values used in the table are taken from a common print train that does contain them. Other than those characters, the print train values are not filled in, but appear to provide some of the motivation for the historical choice of translations reflected here.

The Standard EBCDIC table provides a 1:1 translation for all 256 bytes.

The IBM EBCDIC table does not provide such a translation. The marked cells in the tables differ in such a way that:

1. EBCDIC 0112 ('¢') and 0152 (broken pipe) do not appear in the table.
2. EBCDIC 0137 ('¬') translates to/from ASCII 0236 ('^'). In the standard table, EBCDIC 0232 (no graphic) is used.
3. EBCDIC 0241 ('~') translates to/from ASCII 0176 ('~'). In the standard table, EBCDIC 0137 ('¬') is used.
4. 0255 ('[') and 0275 (']') appear twice, once in the same place as for the standard table and once in place of 0112 ('¢') and 0241 ('~').

In net result:

EBCDIC 0275 (']') displaced EBCDIC 0241 ('~') in cell 0345.

That displaced EBCDIC 0137 ('¬') in cell 0176.

That displaced EBCDIC 0232 (no graphic) in cell 0136.

That replaced EBCDIC 0152 (broken pipe) in cell 0313.

EBCDIC 0255 ('[') replaced EBCDIC 0112 ('¢').

This translation, however, reflects historical practice that (ASCII) '~' and '¬' were often mapped to each other, as were '[' and '¢'; and ']' and (EBCDIC) '~'.

The **cbs** operand is required if any of the **ascii**, **ebcdic**, or **ibm** operands are specified. For the **ascii** operand, the input is handled as described for the **unblock** operand except that characters are converted to ASCII before the trailing <space>s are deleted. For the **ebcdic** and **ibm** operands, the input is handled as described for the **block** operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing <space>s are added.

The **block** and **unblock** keywords are from historical BSD practice.

The consistent use of the word **record** in standard error messages matches most historical practice. An earlier version of System V used **block**, but this has been updated in more recent releases.

Early proposals only allowed two numbers separated by **x** to be used in a product when specifying **bs**=, **cbs**=, **ibs**=, and **obs**= sizes. This was changed to reflect the historical practice of allowing multiple numbers in the product as provided by Version 7 and all releases of System V and BSD.

A change to the *swab* conversion is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #03 and #04, submitted for the ISO POSIX-2: 1993 standard.

A change to the handling of SIGINT is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #06 submitted for the ISO POSIX-2: 1993 standard.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

The second paragraph of the **cbs**= description is reworded and marked EX.

FUTURE DIRECTIONS section added.

Issue 6

Changes are made to *swab* conversion and SIGINT handling to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

11834 **NAME**

11835 delta — make a delta (change) to an SCCS file (**DEVELOPMENT**)

11836 **SYNOPSIS**

11837 XSI `delta [-nps][-g list][-m mrlist][-r SID][-y[comment]] file...`

11838

11839 **DESCRIPTION**

11840 The *delta* utility shall be used to permanently introduce into the named SCCS files changes that
11841 were made to the files retrieved by *get* (called the *g-files*, or generated files).

11842 **OPTIONS**

11843 The *delta* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section |
11844 12.2, Utility Syntax Guidelines, except that the **-y** option has an optional option-argument. This |
11845 optional option-argument cannot be presented as a separate argument.

11846 The following options shall be supported:

11847 **-r** *SID* Uniquely identify which delta is to be made to the SCCS file. The use of this option
11848 is necessary only if two or more outstanding *get* commands for editing (*get* **-e**) on
11849 the same SCCS file were done by the same person (login name). The SID value
11850 specified with the **-r** option can be either the SID specified on the *get* command
11851 line or the SID to be made as reported by the *get* utility; see *get* (on page 2685).

11852 **-s** Suppress the report to standard output of the activity associated with each *file*.
11853 See the STDOUT section.

11854 **-n** Specify retention of the edited *g-file* (normally removed at completion of delta
11855 processing).

11856 **-g** *list* Specify a *list*, (see *get* (on page 2685) for the definition of *list*) of deltas that shall be
11857 ignored when the file is accessed at the change level (SID) created by this delta.

11858 **-m** *mrlist* Specify a modification request (MR) number that the application shall supply as
11859 the reason for creating the new delta. This is used if the SCCS file has the **v** flag set; |
11860 see *admin* (on page 2340).

11861 If **-m** is not used and the standard input is a terminal, the prompt described in the |
11862 STDOUT section shall be written to standard output before the standard input is |
11863 read; if the standard input is not a terminal, no prompt shall be issued. |

11864 MRs in a list shall be separated by <blank>s. An unescaped <newline> character |
11865 shall terminate the MR list. |

11866 If the **v** flag has a value, it shall be taken to be the name of a program which |
11867 validates the correctness of the MR numbers. If a non-zero exit status is returned |
11868 from the MR number validation program, the *delta* utility shall terminate. (It is |
11869 assumed that the MR numbers were not all valid.) |

11870 **-y[***comment***]** Describe the reason for making the delta. The *comment* shall be an arbitrary group |
11871 of lines that would meet the definition of a text file. Implementations shall support |
11872 *comment*s from zero to 512 bytes and may support longer values. A null string
11873 (specified as either **-y**, **-y""**, or in response to a prompt for a comment) is
11874 considered a valid *comment*.

11875 If **-y** is not specified and the standard input is a terminal, the prompt described in |
11876 the STDOUT section shall be written to standard output before the standard input |
11877 is read; if the standard input is not a terminal, no prompt shall be issued. An |
11878 unescaped <newline> character terminates the comment text. |

The **−y** option shall be required if the *file* operand is specified as `'−'`.

−p Write (to standard output) the SCCS file differences before and after the delta is applied in *diff* format; see *diff* (on page 2529).

OPERANDS

The following operand shall be supported:

file A path name of an existing SCCS file or a directory. If *file* is a directory, the *delta* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s.**) and unreadable files shall be silently ignored.

If a single instance *file* is specified as `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only in the following cases:

- To read an *mrlist* or a *command* (see the **−m** and **−y** options).
- A *file* operand is specified as `'−'`.

INPUT FILES

Input files shall be text files whose data is to be included in the SCCS files. If the first character of any line of an input file is SOH (binary 001), the results are unspecified.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *delta*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used only for the following messages in the POSIX locale:

- Prompts (see the **−m** and **−y** options) in the following formats:

```
"MRs? "
```

11921 `"comments? "`

11922 The MR prompt, if written, shall always precede the comments prompt.

11923 • A report of each *file*'s activities (unless the **–s** option is specified) in the following format:

11924 `"%s\n%d inserted\n%d deleted\n%d unchanged\n", <New SID>,`
11925 `<number of lines inserted>, <number of lines deleted>,`
11926 `<number of lines unchanged>`

11927 **STDERR**

11928 Used only for diagnostic messages.

11929 **OUTPUT FILES**

11930 Any SCCS files updated are files of an unspecified format.

11931 **EXTENDED DESCRIPTION**

11932 None.

11933 **EXIT STATUS**

11934 The following exit values shall be returned:

11935 0 Successful completion.

11936 >0 An error occurred.

11937 **CONSEQUENCES OF ERRORS**

11938 Default.

11939 **APPLICATION USAGE**

11940 None.

11941 **EXAMPLES**

11942 None.

11943 **RATIONALE**

11944 None.

11945 **FUTURE DIRECTIONS**

11946 None.

11947 **SEE ALSO**

11948 *admin*, *diff*, *get*, *prs*, *rmdel*

11949 **CHANGE HISTORY**

11950 First released in Issue 2.

11951 **Issue 4**

11952 Format reorganized.

11953 Exceptions to Utility Syntax Guidelines conformance noted.

11954 Internationalized environment variable support mandated.

11955 **Issue 5**

11956 The output format description in the STDOUT section is corrected.

11957 **Issue 6**

11958 The APPLICATION USAGE section is added.

11959 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

11960 The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements.

NAME

df — report free disk space

SYNOPSIS

UP XSI `df [–k][–P|–t][file...]`

DESCRIPTION

XSI The *df* utility shall write the amount of available space and file slots for file systems on which the invoking user has appropriate read access. File systems shall be specified by the *file* operands; when none are specified, information shall be written for all file systems. The format of the default output from *df* is unspecified, but all space figures are reported in 512-byte units, unless the **–k** option is specified. This output shall contain at least the file system names, amount of XSI available space on each of these file systems, and the number of free file slots, or *inodes*, available; when **–t** is specified, the output contains the total allocated space as well.

OPTIONS

The *df* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–k Use 1024-byte units, instead of the default 512-byte units, when writing space figures.

–P Produce output in the format described in the STDOUT section.

XSI **–t** Include total allocated-space figures in the output.

OPERANDS

The following operand shall be supported:

file A path name of a file within the hierarchy of the desired file system. If a file other XSI than a FIFO, a regular file, a directory or a special file representing the device containing the file system (for example, **/dev/dsk/0s1**) is specified, the results are unspecified. Otherwise, *df* shall write the amount of free space in the file system containing the specified *file* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *df*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

12005 *LC_MESSAGES*
12006 Determine the locale that should be used to affect the format and contents of
12007 diagnostic messages written to standard error and informative messages written to
12008 standard output.

12009 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

12010 **ASYNCHRONOUS EVENTS**
12011 Default.

12012 **STDOUT**
12013 When both the –**k** and –**P** options are specified, the following header line shall be written (in the
12014 POSIX locale):

12015 `"Filesystem 1024-blocks Used Available Capacity Mounted on\n"`

12016 When the –**P** option is specified without the –**k** option, the following header line shall be written
12017 (in the POSIX locale):

12018 `"Filesystem 512-blocks Used Available Capacity Mounted on\n"`

12019 The implementation may adjust the spacing of the header line and the individual data lines so
12020 that the information is presented in orderly columns.

12021 The remaining output with –**P** shall consist of one line of information for each specified file
12022 system. These lines shall be formatted as follows:

12023 `"%s %d %d %d %d%% %s\n", <file system name>, <total space>,`
12024 `<space used>, <space free>, <percentage used>,`
12025 `<file system root>`

12026 In the following list, all quantities expressed in 512-byte units (1 024-byte when –**k** is specified)
12027 shall be rounded up to the next higher unit. The fields are:

12028 *<file system name>*
12029 The name of the file system, in an implementation-defined format.

12030 *<total space>* The total size of the file system in 512-byte units. The exact meaning of this figure
12031 is implementation-defined, but should include *<space used>*, *<space free>*, plus any
12032 space reserved by the system not normally available to a user.

12033 *<space used>* The total amount of space allocated to existing files in the file system, in 512-byte
12034 units.

12035 *<space free>* The total amount of space available within the file system for the creation of new
12036 files by unprivileged users, in 512-byte units. When this figure is less than or equal
12037 to zero, it shall not be possible to create any new files on the file system without
12038 first deleting others, unless the process has appropriate privileges. The figure
12039 written may be less than zero.

12040 *<percentage used>*
12041 The percentage of the normally available space that is currently allocated to all
12042 files on the file system. This shall be calculated using the fraction:

12043 `<space used>/( <space used>+ <space free>)`

12044 expressed as a percentage. This percentage may be greater than 100 if *<space free>*
12045 is less than zero. The percentage value shall be expressed as a positive integer,
12046 with any fractional result causing it to be rounded to the next highest integer.

<file system root>
The directory below which the file system hierarchy appears.

XSI The output format is unspecified when **–t** is used.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
On most systems, the ‘‘name of the file system, in an implementation-defined format’’ is the special file on which the file system is mounted.

On large file systems, the calculation specified for percentage used can create huge rounding errors.

EXAMPLES

1. The following example writes portable information about the **/usr** file system:

   ```
   df –P /usr
   ```

2. Assuming that **/usr/src** is part of the **/usr** file system, the following produces the same output as the previous example:

   ```
   df –P /usr/src
   ```

RATIONALE
The behavior of *df* with the **–P** option is the default action of the 4.2 BSD *df* utility. The uppercase **–P** was selected to avoid collision with a known industry extension using **–p**.

Historical *df* implementations vary considerably in their default output. It was therefore necessary to describe the default output in a loose manner to accommodate all known historical implementations and to add a portable option (**–P**) to provide information in a portable format.

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of IEEE Std. 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The **–k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and that a **–k** option to switch to 1 024-byte units was a good compromise. Users who prefer the more logical 1 024-byte quantity can easily alias *df* to *df* **–k** without breaking many historical scripts relying on the 512-byte units.

It was suggested that *df* and the various related utilities be modified to access a *BLOCKSIZE* environment variable to achieve consistency and user acceptance. Since this is not historical practice on any system, it is left as a possible area for system extensions and will be re-evaluated

in a future version if it is widely implemented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

12101 **NAME**

12102 diff — compare two files

12103 **SYNOPSIS**

12104 `diff [-c| -e| -f| -C n][-br] file1 file2`

12105 **DESCRIPTION**

12106 The *diff* utility shall compare the contents of *file1* and *file2* and write to standard output a list of
12107 changes necessary to convert *file1* into *file2*. This list should be minimal. No output shall be
12108 produced if the files are identical.

12109 **OPTIONS**

12110 The *diff* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
12111 12.2, Utility Syntax Guidelines.

12112 The following options shall be supported:

12113 **-b** Cause any amount of white space at the end of a line to be treated as a single
12114 <newline> character (that is, the white-space characters preceding the <newline>
12115 character are ignored) and other strings of white-space characters, not including
12116 <newline> characters, to compare equal.

12117 **-c** Produce output in a form that provides three lines of context.

12118 **-C n** Produce output in a form that provides *n* lines of context (where *n* shall be
12119 interpreted as a positive decimal integer).

12120 **-e** Produce output in a form suitable as input for the *ed* utility, which can then be
12121 used to convert *file1* into *file2*.

12122 **-f** Produce output in an alternative form, similar in format to **-e**, but not intended to
12123 be suitable as input for the *ed* utility, and in the opposite order.

12124 **-r** Apply *diff* recursively to files and directories of the same name when *file1* and *file2*
12125 are both directories.

12126 **OPERANDS**

12127 The following operands shall be supported:

12128 *file1*, *file2* A path name of a file to be compared. If either the *file1* or *file2* operand is `'-'`, the
12129 standard input shall be used in its place.

12130 If both *file1* and *file2* are directories, *diff* shall not compare block special files, character special
12131 files, or FIFO special files to any files and shall not compare regular files to directories. The
12132 system documentation shall specify the behavior of *diff* on implementation-defined file types not
12133 specified by the System Interfaces volume of IEEE Std. 1003.1-200x when found in directories.
12134 Further details are as specified in **Diff Directory Comparison Format** (on page 2530).

12135 If only one of *file1* and *file2* is a directory, *diff* shall be applied to the non-directory file and the file
12136 contained in the directory file with a file name that is the same as the last component of the non-
12137 directory file.

12138 **STDIN**

12139 The standard input shall be used only if one of the *file1* or *file2* operands references standard
12140 input. See the INPUT FILES section.

12141 **INPUT FILES**

12142 The input files shall be text files.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 75 proposes adding the following text: "If a file which is not a text file is encountered, a binary comparison shall be performed, and if they are not identical, an unspecified message containing the two file names and the string "differ" shall be produced." The reviewers agreed in principle; however, this change needs further cleanup such as the locale and output formats specifying before it can be made.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *diff*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LC_TIME Determine the locale for affecting the format of file timestamps written with the **–C** and **–c** options.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the locale for affecting the timezone used for calculating file timestamps written with the **–C** and **–c** options.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Diff Directory Comparison Format

If both *file1* and *file2* are directories, the following output formats shall be used.

In the POSIX locale, each file that is present in only one directory shall be reported using the following format:

```
"Only in %s: %s\n", <directory pathname>, <filename>
```

In the POSIX locale, subdirectories that are common to the two directories may be reported with the following format:

```
"Common subdirectories: %s and %s\n", <directory1 pathname>,
    <directory2 pathname>
```

For each file common to the two directories if the two files are not to be compared, the following format shall be used in the POSIX locale:

12185 "File %s is a %s while file %s is a %s\n", <*directory1 pathname*>,
12186 <*file type of directory1 pathname*>, <*directory2 pathname*>,
12187 <*file type of directory2 pathname*>

12188 For each file common to the two directories, if the files are compared and are identical, no output
12189 shall be written. If the two files differ, the following format is written:

12190 "diff %s %s %s\n", <*diff_options*>, <*filename1*>, <*filename2*>

12191 where <*diff_options*> are the options as specified on the command line. Depending on these
12192 options, one of the following output formats shall be used to write the differences.

12193 All directory path names listed in this section shall be relative to the original command line
12194 arguments. All other names of files listed in this section are file names (path name components).

12195 **Diff Default Output Format**

12196 The default (without **–e**, **–f**, **–c**, or **–C** options) *diff* utility output shall contain lines of these |
12197 forms:

12198 "%da%d\n", <*num1*>, <*num2*>

12199 "%da%d,%d\n", <*num1*>, <*num2*>, <*num3*>

12200 "%dd%d\n", <*num1*>, <*num2*>

12201 "%d,%dd%d\n", <*num1*>, <*num2*>, <*num3*>

12202 "%dc%d\n", <*num1*>, <*num2*>

12203 "%d,%dc%d\n", <*num1*>, <*num2*>, <*num3*>

12204 "%dc%d,%d\n", <*num1*>, <*num2*>, <*num3*>

12205 "%d,%dc%d,%d\n", <*num1*>, <*num2*>, <*num3*>, <*num4*>

12206 These lines resemble *ed* subcommands to convert *file1* into *file2*. The line numbers before the
12207 action letters shall pertain to *file1*; those after shall pertain to *file2*. Thus, by exchanging *a* for *d*
12208 and reading the line in reverse order, one can also determine how to convert *file2* into *file1*. As in
12209 *ed*, identical pairs (where *num1*= *num2*) are abbreviated as a single number.

12210 Following each of these lines, *diff* shall write to standard output all lines affected in the first file
12211 using the format:

12212 "<Δ%s", <*line*>

12213 and all lines affected in the second file using the format:

12214 ">Δ%s", <*line*>

12215 If there are lines affected in both *file1* and *file2* (as with the **c** subcommand), the changes are
12216 separated with a line consisting of three hyphens:

12217 "–––\n"

12218 **Diff –e Output Format**

12219 With the **–e** option, a script shall be produced that shall, when provided as input to *ed*, along
12220 with an appended **w** (write) command, convert *file1* into *file2*. Only the **a** (append), **c** (change), **d**
12221 (delete), **i** (insert), and **s** (substitute) commands of *ed* shall be used in this script. Text lines,
12222 except those consisting of the single character period (`'.'`), shall be output as they appear in the
12223 file.

12224 **Diff –f Output Format**

12225 With the **–f** option, an alternative format of script shall be produced. It is similar to that
12226 produced by **–e**, with the following differences:

12227 1. It is expressed in reverse sequence; the output of **–e** orders changes from the end of the file
12228 to the beginning; the **–f** from beginning to end.

12229 2. The command form <*lines*> <*command-letter*> used by **–e** is reversed. For example,
12230 10*c* with **–e** would be *c*10 with **–f**.

12231 3. The form used for ranges of line numbers is <space> character-separated, rather than
12232 comma-separated.

12233 **Diff –c or –C Output Format**

12234 With the **–c** or **–C** option, the output format shall consist of affected lines along with
12235 surrounding lines of context. The affected lines shall show which ones need to be deleted or
12236 changed in *file1*, and those added from *file2*. With the **–c** option, three lines of context, if
12237 available, shall be written before and after the affected lines. With the **–C** option, the user can
12238 specify how many lines of context are written. The exact format follows.

12239 The name and last modification time of each file shall be output in the following format:

12240 `"*** %s %s\n", file1, <file1 timestamp>`
12241 `"––– %s %s\n", file2, <file2 timestamp>`

12242 Each <*file*> field shall be the path name of the corresponding file being compared. The path
12243 name written for standard input is unspecified.

12244 In the POSIX locale, each <*timestamp*> field shall be equivalent to the output from the following
12245 command:

12246 `date "+%a %b %e %T %Y"`

12247 without the trailing <newline> character, executed at the time of last modification of the
12248 corresponding file (or the current time, if the file is standard input).

12249 Then, the following output formats shall be applied for every set of changes.

12250 First, a line shall be written in the following format:

12251 `"***************\n"`

12252 Next, the range of lines in *file1* shall be written in the following format:

12253 `"*** %d,%d ****\n", <beginning line number>, <ending line number>`

12254 Next, the affected lines along with lines of context (unaffected lines) shall be written. Unaffected
12255 lines shall be written in the following format:

12256 `"ΔΔ%s", <unaffected_line>`

Deleted lines shall be written as:

"–Δ%s", <*deleted_line*>

Changed lines shall be written as:

"!Δ%s", <*changed_line*>

Next, the range of lines in *file2* shall be written in the following format:

"––– %d,%d ––––\n", <*beginning line number*>, <*ending line number*>

Then, lines of context and changed lines shall be written as described in the previous formats. Lines added from *file2* shall be written in the following format:

"+Δ%s", <*added_line*>

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 No differences were found.

1 Differences were found.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If lines at the end of a file are changed and other lines are added, *diff* output may show this as a delete and add, as a change, or as a change and add; *diff* is not expected to know which happened and users should not care about the difference in output as long as it clearly shows the differences between the files.

EXAMPLES

If **dir1** is a directory containing a directory named **x**, **dir2** is a directory containing a directory named **x**, **dir1/x** and **dir2/x** both contain files named **date.out**, and **dir2/x** contains a file named **y**, the command:

```
diff –r dir1 dir2
```

could produce output similar to:

```
Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
diff –r dir1/x/date.out dir2/x/date.out
1c1
< Mon Jul  2 13:12:16 PDT 1990
–––
> Tue Jun 19 21:41:39 PDT 1990
```

12297 **RATIONALE**

12298 The **–h** option was omitted because it was insufficiently specified and does not add to
12299 applications portability.

12300 Historical implementations employ algorithms that do not always produce a minimum list of
12301 differences; the current language about making every effort is the best this volume of
12302 IEEE Std. 1003.1-200x can do, as there is no metric that could be employed to judge the quality of
12303 implementations against any and all file contents. The statement ''This list should be minimal''
12304 clearly implies that implementations are not expected to provide the following output when
12305 comparing two 100-line files that differ in only one character on a single line:

12306 ```
1,100c1,100
12307 all 100 lines from file1 preceded with "< "
12308 ---
12309 all 100 lines from file2 preceded with "> "
```

12310 The ''Only in'' messages required when the **–r** option is specified are not used by most historical
12311 implementations if the **–e** option is also specified. It is required here because it provides useful
12312 information that must be provided to update a target directory hierarchy to match a source
12313 hierarchy. The ''Common subdirectories'' messages are written by System V and 4.3 BSD when
12314 the **–r** option is specified. They are allowed here but are not required because they are reporting
12315 on something that is the same, not reporting a difference, and are not needed to update a target
12316 hierarchy.

12317 The **–c** option, which writes output in a format using lines of context, has been included. The
12318 format is useful for a variety of reasons, among them being much improved readability and the
12319 ability to understand difference changes when the target file has line numbers that differ from
12320 another similar, but slightly different, copy. The *patch* utility is most valuable when working
12321 with difference listings using the context format. The BSD version of **–c** takes an optional
12322 argument specifying the amount of context. Rather than overloading **–c** and breaking the Utility
12323 Syntax Guidelines for *diff*, the standard developers decided to add a separate option for
12324 specifying a context diff with a specified amount of context (**–C**). Also, the format for context
12325 *diff*s was extended slightly in 4.3 BSD to allow multiple changes that are within context lines
12326 from each other to be merged together. The output format contains an additional four asterisks
12327 after the range of affected lines in the first file name. This was to provide a flag for old programs
12328 (like old versions of *patch*) that only understand the old context format. The version of context
12329 described here does not require that multiple changes within context lines be merged, but it does
12330 not prohibit it either. The extension is upward-compatible, so any vendors that wish to retain the
12331 old version of *diff* can do so by adding the extra four asterisks (that is, utilities that currently use
12332 *diff* and understand the new merged format will also understand the old unmerged format, but
12333 not *vice versa*).

12334 The substitute command was added as an additional format for the **–e** option. This was added to
12335 provide implementations a way to fix the classic ''dot alone on a line'' bug present in many
12336 versions of *diff*. Since many implementations have fixed this bug, the standard developers
12337 decided not to standardize broken behavior, but rather to provide the necessary tool for fixing
12338 the bug. One way to fix this bug is to output two periods whenever a lone period is needed, then
12339 terminate the append command with a period, and then use the substitute command to convert
12340 the two periods into one period.

12341 The BSD-derived **–r** option was added to provide a mechanism for using *diff* to compare two file
12342 system trees. This behavior is useful, is standard practice on all BSD-derived systems, and is not
12343 easily reproducible with the *find* utility.

12344 The requirement that *diff* not compare files in some circumstances, even though they have the
12345 same name, is based on the actual output of historical implementations. The message specified
```

here is already in use when a directory is being compared to a non-directory. It is extended here to preclude the problems arising from running into FIFOs and other files that would cause *diff* to hang waiting for input with no indication to the user that *diff* was hung. In most common usage, *diff* **–r** should indicate differences in the file hierarchies, not the difference of contents of devices pointed to by the hierarchies.

Many early implementations of *diff* require seekable files. Since the System Interfaces volume of IEEE Std. 1003.1-200x supports named pipes, the standard developers decided that such a restriction was unreasonable. Note also that the allowed file name – almost always refers to a pipe.

No directory search order is specified for *diff*. The historical ordering is, in fact, not optimal, in that it prints out all of the differences at the current level, including the statements about all common subdirectories before recursing into those subdirectories.

The message:

`"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>`

does not vary by locale because it is the representation of a command, not an English sentence.

FUTURE DIRECTIONS

None.

cmp, *comm*, *ed*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–f** option is added.

The output format for **–c** or **–C** format is changed to align with changes to the IEEE P1003.2b draft standard resulting from IEEE PASC Interpretation 1003.2 #71.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

12378 **NAME**

12379 dirname — return the directory portion of path name

12380 **SYNOPSIS**

12381 `dirname` *`string`*

12382 **DESCRIPTION**

12383 The *string* operand shall be treated as a path name, as defined in the Base Definitions volume of
12384 IEEE Std. 1003.1-200x, Section 3.268, Path Name. The string *string* shall be converted to the name
12385 of the directory containing the file name corresponding to the last path name component in
12386 *string*, performing actions equivalent to the following steps in order:

12387 1. If *string* is //, skip steps 2 to 5.

12388 2. If *string* consists entirely of slash characters, *string* shall be set to a single slash character. In
12389 this case, skip steps 3 to 8.

12390 3. If there are any trailing slash characters in *string*, they shall be removed.

12391 4. If there are no slash characters remaining in *string*, *string* shall be set to a single period
12392 character. In this case, skip steps 5 to 8.

12393 5. If there are any trailing non-slash characters in *string*, they shall be removed.

12394 6. If the remaining *string* is //, it is implementation-defined whether steps 7 and 8 are skipped
12395 or processed.

12396 7. If there are any trailing slash characters in *string*, they shall be removed.

12397 8. If the remaining *string* is empty, *string* shall be set to a single slash character.

12398 The resulting string shall be written to standard output.

12399 **OPTIONS**

12400 None.

12401 **OPERANDS**

12402 The following operand shall be supported:

12403 *string* A string.

12404 **STDIN**

12405 Not used.

12406 **INPUT FILES**

12407 None.

12408 **ENVIRONMENT VARIABLES**

12409 The following environment variables shall affect the execution of *dirname*:

12410 *LANG* Provide a default value for the internationalization variables that are unset or null.
12411 If *LANG* is unset or null, the corresponding value from the implementation-
12412 defined default locale will be used. If any of the internationalization variables
12413 contains an invalid setting, the utility shall behave as if none of the variables had
12414 been defined.

12415 *LC_ALL* If set to a non-empty string value, override the values of all the other
12416 internationalization variables.

12417 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
12418 characters (for example, single-byte as opposed to multi-byte characters in
12419 arguments).

12420 *LC_MESSAGES*
12421 Determine the locale that should be used to affect the format and contents of
12422 diagnostic messages written to standard error.

12423 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

12424 **ASYNCHRONOUS EVENTS**
12425 Default.

12426 **STDOUT**
12427 The *dirname* utility shall write a line to the standard output in the following format:

12428 `"%s\n", <resulting string>`

12429 **STDERR**
12430 Used only for diagnostic messages.

12431 **OUTPUT FILES**
12432 None.

12433 **EXTENDED DESCRIPTION**
12434 None.

12435 **EXIT STATUS**
12436 The following exit values shall be returned:

12437 0 Successful completion.

12438 >0 An error occurred.

12439 **CONSEQUENCES OF ERRORS**
12440 Default.

12441 **APPLICATION USAGE**
12442 The definition of *pathname* specifies implementation-defined behavior for path names starting |
12443 with two slash characters. Therefore, applications shall not arbitrarily add slashes to the |
12444 beginning of a path name unless they can ensure that there are more or less than two or are |
12445 prepared to deal with the implementation-defined consequences. |

12446 **EXAMPLES**

12447

Command	Results
dirname /	/
dirname / /	/ or / /
dirname /*a*/*b*/	/*a*
dirname / /*a*/ /*b*/ /	/ /*a*
dirname	Unspecified
dirname a	. ($? = 0)
dirname ""	. ($? = 0)
dirname /*a*	/
dirname /*a*/*b*	/*a*
dirname a/*b*	*a*

12458 **RATIONALE**
12459 The *dirname* utility originated in System III. It has evolved through the System V releases to a
12460 version that matches the requirements specified in this description in System V Release 3. 4.3
12461 BSD and earlier versions did not include *dirname*.

12462 The behaviors of *basename* and *dirname* in this volume of IEEE Std. 1003.1-200x have been
12463 coordinated so that when *string* is a valid path name:

12464 `$(basename "`*`string`*`")`

12465 would be a valid file name for the file in the directory:

12466 `$(dirname "`*`string`*`")`

12467 This would not work for the versions of these utilities in early proposals due to the way
12468 processing of trailing slashes was specified. Consideration was given to leaving processing
12469 unspecified if there were trailing slashes, but this cannot be done; the Base Definitions volume of |
12470 IEEE Std. 1003.1-200x, Section 3.268, Path Name allows trailing slashes. The *basename* and |
12471 *dirname* utilities have to specify consistent handling for all valid path names.

12472 **FUTURE DIRECTIONS**

12473 None.

12474 **SEE ALSO**

12475 *basename*, Section 2.5 (on page 2241)

12476 **CHANGE HISTORY**

12477 First released in Issue 2.

12478 **Issue 4**

12479 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

du — estimate file space usage

SYNOPSIS

UP

```
du [–a | –s][–kx][–H | –L][file ...]
```

DESCRIPTION

By default, the *du* utility shall write to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. By default, when a symbolic link is encountered on the command line or in the file hierarchy, *du* shall count the size of the symbolic link (rather than the file referenced by the link), and shall not follow the link to another portion of the file hierarchy. The size of the file space allocated to a file of type directory shall be defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.

When *du* cannot *stat*( ) files or *stat*( ) or read directories, it shall report an error condition and the final exit status is affected. Files with multiple links shall be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes shall be written in 512-byte units, rounded up to the next 512-byte unit.

OPTIONS

The *du* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–a In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the **–a** option, non-directories given as *file* operands shall always be listed.

–H If a symbolic link is specified on the command line, *du* shall count the size of the file or file hierarchy referenced by the link.

–k Write the files sizes in units of 1 024 bytes, rather than the default 512-byte units.

–L If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *du* shall count the size of the file or file hierarchy referenced by the link.

–s Instead of the default output, report only the total sum for each of the specified files.

–x When evaluating file sizes, evaluate only those files that have the same device as the file specified by the *file* operand.

Specifying more than one of the mutually-exclusive options **–H** and **–L** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operand shall be supported:

file The path name of a file whose size is to be written. If no *file* is specified, the current directory shall be used.

STDIN

Not used.

12522 **INPUT FILES**

12523 None.

12524 **ENVIRONMENT VARIABLES**

12525 The following environment variables shall affect the execution of *du*:

12526 *LANG* Provide a default value for the internationalization variables that are unset or null.
12527 If *LANG* is unset or null, the corresponding value from the implementation-
12528 defined default locale shall be used. If any of the internationalization variables
12529 contains an invalid setting, the utility shall behave as if none of the variables had
12530 been defined.

12531 *LC_ALL* If set to a non-empty string value, override the values of all the other
12532 internationalization variables.

12533 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
12534 characters (for example, single-byte as opposed to multi-byte characters in
12535 arguments).

12536 *LC_MESSAGES*
12537 Determine the locale that should be used to affect the format and contents of
12538 diagnostic messages written to standard error.

12539 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

12540 **ASYNCHRONOUS EVENTS**

12541 Default.

12542 **STDOUT**

12543 The output from *du* shall consist of the amount of the space allocated to a file and the name of
12544 the file, in the following format:

12545 `"%d %s\n", <size>, <pathname>`

12546 **STDERR**

12547 Used only for diagnostic messages.

12548 **OUTPUT FILES**

12549 None.

12550 **EXTENDED DESCRIPTION**

12551 None.

12552 **EXIT STATUS**

12553 The following exit values shall be returned:

12554 0 Successful completion.

12555 >0 An error occurred.

12556 **CONSEQUENCES OF ERRORS**

12557 Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of IEEE Std. 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The **–k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and that a **–k** option to switch to 1 024-byte units was a good compromise. Users who prefer the 1 024-byte quantity can easily alias *du* to *du* **–k** without breaking the many historical scripts relying on the 512-byte units.

The **–b** option was added to an early proposal to provide a resolution to the situation where System V and BSD systems give figures for file sizes in *blocks*, which is an implementation-defined concept. (In common usage, the block size is 512 bytes for System V and 1 024 bytes for BSD systems.) However, **–b** was later deleted, since the default was eventually decided as 512-byte units.

Historical file systems provided no way to obtain exact figures for the space allocation given to files. There are two known areas of inaccuracies in historical file systems: cases of *indirect blocks* being used by the file system or *sparse* files yielding incorrectly high values. An indirect block is space used by the file system in the storage of the file, but that need not be counted in the space allocated to the file. A *sparse* file is one in which an *lseek*( ) call has been made to a position beyond the end of the file and data has subsequently been written at that point. A file system need not allocate all the intervening zero-filled blocks to such a file. It is up to the implementation to define exactly how accurate its methods are.

The **–a** and **–s** options were mutually-exclusive in the original version of *du*. The POSIX Shell and Utilities description is implied by the language in the SVID where **–s** is described as causing ‘‘only the grand total’’ to be reported. Some systems may produce output for **–sa**, but a Strictly Conforming POSIX Shell and Utilities Application cannot use that combination.

The **–a** and **–s** options were adopted from the SVID except that the System V behavior of not listing non-directories explicitly given as operands, unless the **–a** option is specified, was considered a bug; the BSD-based behavior (report for all operands) is mandated. The default behavior of *du* in the SVID with regard to reporting the failure to read files (it produces no messages) was considered counter-intuitive, and thus it was specified that the POSIX Shell and Utilities default behavior shall be to produce such messages. These messages can be turned off with shell redirection to achieve the System V behavior.

The **–x** option is historical practice on recent BSD systems. It has been adopted by this volume of IEEE Std. 1003.1-200x because there was no other historical method of limiting the *du* search to a single file hierarchy. This limitation of the search is necessary to make it possible to obtain file space usage information about a file system on which other file systems are mounted, without having to resort to a lengthy *find* and *awk* script.

FUTURE DIRECTIONS

None.

12603 *ls*

12604 **CHANGE HISTORY**

12605 First released in Issue 2.

12606 **Issue 4**

12607 Aligned with the ISO / IEC 9945-2: 1993 standard.

12608 **Issue 6**

12609 This utility is now marked as part of the User Portability Utilities option.

12610 The APPLICATION USAGE section is added.

12611 This utility is reinstated, as the LEGACY marking was incorrect in Issue 5.

12612 The obsolescent **–r** option has been removed.

12613 The Open Group corrigenda item U025 / 3 has been applied. The *du* utility had incorrectly been
12614 marked LEGACY.

12615 The **–H** and **–L** options for symbolic links are added as described in the IEEE P1003.2b draft
12616 standard.

12617 **NAME**

12618 echo — write arguments to standard output

12619 **SYNOPSIS**

12620 `echo [`*`string ...`*`]`

12621 **DESCRIPTION**

12622 The *echo* utility writes its arguments to standard output, followed by a <newline> character. If
12623 there are no arguments, only the <newline> character is written.

12624 **OPTIONS**

12625 The *echo* utility shall not recognize the "––" argument in the manner specified by Guideline 10 |
12626 of the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines; |
12627 "––" shall be recognized as a string operand.

12628 Implementations shall not support any options. |

12629 **OPERANDS**

12630 The following operands shall be supported:

12631 *string* A string to be written to standard output. If any operand is –**n**, it shall be treated as |
12632 a string, not an option. The following character sequences shall be recognized
12633 within any of the arguments:

12634 `\a` Write an <alert> character.

12635 `\b` Write a <backspace> character.

12636 `\c` Suppress the <newline> character that otherwise follows the final
12637 argument in the output. All characters following the `'\c'` in the
12638 arguments shall be ignored.

12639 `\f` Write a <form-feed> character.

12640 `\n` Write a <newline> character.

12641 `\r` Write a <carriage-return> character.

12642 `\t` Write a <tab> character.

12643 `\v` Write a <vertical-tab> character.

12644 `\\` Write a backslash character.

12645 `\0`*`num`* Write an 8-bit value that is the zero, one, two, or three-digit octal number
12646 *num*. |

12647 **STDIN**

12648 Not used.

12649 **INPUT FILES**

12650 None.

12651 **ENVIRONMENT VARIABLES**

12652 The following environment variables shall affect the execution of *echo*:

12653 *LANG* Provide a default value for the internationalization variables that are unset or null.
12654 If *LANG* is unset or null, the corresponding value from the implementation- |
12655 defined default locale shall be used. If any of the internationalization variables |
12656 contains an invalid setting, the utility shall behave as if none of the variables had
12657 been defined.

12658 *LC_ALL* If set to a non-empty string value, override the values of all the other
12659 internationalization variables.

12660 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
12661 characters (for example, single-byte as opposed to multi-byte characters in
12662 arguments).

12663 *LC_MESSAGES*
12664 Determine the locale that should be used to affect the format and contents of
12665 diagnostic messages written to standard error.

12666 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

12667 **ASYNCHRONOUS EVENTS**
12668 Default.

12669 **STDOUT**
12670 The *echo* utility arguments shall be separated by single <space> characters and a <newline>
12671 character follows the last argument. Output transformations shall occur based on the escape
12672 sequences in the input. See the OPERANDS section.

12673 **STDERR**
12674 Used only for diagnostic messages.

12675 **OUTPUT FILES**
12676 None.

12677 **EXTENDED DESCRIPTION**
12678 None.

12679 **EXIT STATUS**
12680 The following exit values shall be returned:

12681 0 Successful completion.

12682 >0 An error occurred.

12683 **CONSEQUENCES OF ERRORS**
12684 Default.

12685 **APPLICATION USAGE**
12686 In the ISO/IEC 9945-2:1993 standard, it was not possible to use *echo* portably across all systems
12687 that were not XSI-conformant unless both **–n** (as the first argument) and escape sequences were
12688 omitted.

12689 The *printf* utility can be used portably to emulate any of the traditional behaviors of the *echo*
12690 utility as follows:

12691 • The historic System V *echo* and the current requirements in this volume of
12692 IEEE Std. 1003.1-200x are equivalent to:

12693 ```
printf "%b\n" "$*"
```

12694 • The BSD *echo* is equivalent to:

12695 ```
if [ "X$1" = "X–n" ]
12696 then
12697     shift
12698     printf "%s" "$*"
12699 else
12700     printf "%s\n" "$*"
```

```
fi
```

New applications are encouraged to use *printf* instead of *echo*.

EXAMPLES

None.

RATIONALE

The *echo* utility has not been made obsolescent because of its extremely widespread use in historical applications. Portable applications that wish to do prompting without <newline>s or that could possibly be expecting to echo a **−n**, should use the new *printf* utility derived from the Ninth Edition system.

As specified, *echo* writes its arguments in the simplest of ways. The two different historical versions of *echo* vary in fatally incompatible ways.

The BSD *echo* checks the first argument for the string **−n** which causes it to suppress the <newline> character that would otherwise follow the final argument in the output.

The System V *echo* does not support any options, but allows escape sequences within its operands, as described in the OPERANDS section.

The *echo* utility does not support Utility Syntax Guideline 10 because historical applications depend on *echo* to echo *all* of its arguments, except for the **−n** option in the BSD version.

FUTURE DIRECTIONS

None.

SEE ALSO

printf

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

In the OPTIONS section, the last sentence is changed to indicate that implementations ‘‘do not’’ support any options; in the previous issue this said ‘‘need not’’.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- A set of character sequences is defined as *string* operands.
- *LC_CTYPE* is added to the list of environment variables affecting *echo*.
- In the OPTIONS section, implementations shall not support any options.

12735 **NAME**

12736 ed — edit text

12737 **SYNOPSIS**

12738 `ed [`–p *string*`][`–s`][`*file*`]`

12739 **DESCRIPTION**

12740 The *ed* utility is a line-oriented text editor that uses two modes: *command mode* and *input mode*.
12741 In command mode the input characters shall be interpreted as commands, and in input mode
12742 they shall be interpreted as text. See the EXTENDED DESCRIPTION section.

12743 **OPTIONS**

12744 The *ed* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, |
12745 Utility Syntax Guidelines. |

12746 The following options shall be supported:

12747 –**p** *string* Use *string* as the prompt string when in command mode. By default, there shall be |
12748 no prompt string.

12749 –**s** Suppress the writing of byte counts by **e**, **E**, **r**, and **w** commands and of the `'!'`
12750 prompt after a !*command*.

12751 **OPERANDS**

12752 The following operand shall be supported:

12753 *file* If the *file* argument is given, *ed* shall simulate an **e** command on the file named by
12754 the path name, *file*, before accepting commands from the standard input. If the *file*
12755 operand is `'–'`, the results are unspecified.

12756 **STDIN**

12757 The standard input shall be a text file consisting of commands, as described in the EXTENDED
12758 DESCRIPTION section.

12759 **INPUT FILES**

12760 The input files shall be text files.

12761 **ENVIRONMENT VARIABLES**

12762 The following environment variables shall affect the execution of *ed*:

12763 *HOME* Determine the path name of the user's home directory.

12764 *LANG* Provide a default value for the internationalization variables that are unset or null.
12765 If *LANG* is unset or null, the corresponding value from the implementation- |
12766 defined default locale shall be used. If any of the internationalization variables |
12767 contains an invalid setting, the utility shall behave as if none of the variables had
12768 been defined.

12769 *LC_ALL* If set to a non-empty string value, override the values of all the other
12770 internationalization variables.

12771 *LC_COLLATE*
12772 Determine the locale for the behavior of ranges, equivalence classes, and multi-
12773 character collating elements within regular expressions.

12774 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
12775 characters (for example, single-byte as opposed to multi-byte characters in
12776 arguments and input files) and the behavior of character classes within regular
12777 expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

The *ed* utility shall take the standard action for all signals (see the ASYNCHRONOUS EVENTS section in Section 1.11 (on page 2224)) with the following exceptions:

SIGINT The *ed* utility shall interrupt its current activity, write the string "?\n" to standard output, and return to command mode (see the EXTENDED DESCRIPTION section).

SIGHUP If the buffer is not empty and has changed since the last write, the *ed* utility shall attempt to write a copy of the buffer in a file. First, the file named **ed.hup** in the current directory shall be used; if that fails, the file named **ed.hup** in the directory named by the *HOME* environment variable shall be used. In any case, the *ed* utility shall exit without returning to command mode.

SIGQUIT The *ed* utility shall ignore this event.

STDOUT

Various editing commands and the prompting feature (see **−p**) write to standard output, as described in the EXTENDED DESCRIPTION section.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

EXTENDED DESCRIPTION

The *ed* utility shall operate on a copy of the file it is editing; changes made to the copy shall have no effect on the file until a **w** (write) command is given. The copy of the text is called the *buffer*.

Commands to *ed* have a simple and regular structure: zero, one, or two *addresses* followed by a single-character *command*, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses very often can be omitted. If the **−p** option is specified, the prompt string shall be written to standard output before each command is read.

In general, only one command can appear on a line. Certain commands allow text to be input. This text is placed in the appropriate place in the buffer. While *ed* is accepting text, it is said to be in *input mode*. In this mode, no commands shall be recognized; all input is merely collected. Input mode is terminated by entering a line consisting of two characters: a period ('.') followed by a <newline> character. This line is not considered part of the input text.

Regular Expressions in ed

The *ed* utility shall support basic regular expressions, as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions. Since regular expressions in *ed* are always matched against single lines, never against any larger section of text, there is no way for a regular expression to match a <newline> character. A null RE shall be equivalent to the last RE encountered.

Regular expressions are used in addresses to specify lines, and in some commands (for example, the **s** substitute command) to specify portions of a line to be substituted.

12823 **Addresses in ed**

12824 Addressing in *ed* relates to the current line. Generally, the current line is the last line affected by a
12825 command. The current line number is the address of the current line. If the edit buffer is not
12826 empty, the initial value for the current line shall be the last line in the edit buffer; otherwise, zero.

12827 Addresses shall be constructed as follows:

12828 1. The period character (`'.'`) shall address the current line.

12829 2. The dollar sign character (`'$'`) shall address the last line of the edit buffer.

12830 3. The positive decimal number *n* shall address the *n*th line of the edit buffer.

12831 4. The apostrophe-x character pair (`"'x"`) shall address the line marked with the mark name
12832 character *x*, which shall be a lowercase letter from the portable character set. It shall be an
12833 error if the character has not been set to mark a line or if the line that was marked is not
12834 currently present in the edit buffer.

12835 5. A BRE enclosed by slash characters (`'/'`) shall address the first line found by searching
12836 forwards from the line following the current line toward the end of the edit buffer and
12837 stopping at the first line containing a string matching the BRE. The BRE consisting of a null
12838 BRE delimited by a pair of slash characters shall address the next line containing the last
12839 BRE encountered. In addition, the second slash can be omitted at the end of a command
12840 line. Within the BRE, a backslash-slash pair (`"\/"`) shall represent a literal slash instead of
12841 the BRE delimiter. If necessary, the search shall wrap around to the beginning of the buffer
12842 and continue up to and including the current line, so that the entire buffer is searched.

12843 6. A BRE enclosed by question-mark characters (`'?'`) shall address the first line found by
12844 searching backwards from the line preceding the current line toward the beginning of the
12845 edit buffer and stopping at the first line containing a string matching the BRE. The BRE
12846 consisting of a null BRE delimited by a pair of question-mark characters (`"??"`) shall
12847 address the previous line containing the last BRE encountered. In addition, the second
12848 question-mark can be omitted at the end of a command line. Within the BRE, a backslash-
12849 question-mark pair (`"\?"`) shall represent a literal question mark instead of the BRE
12850 delimiter. If necessary, the search shall wrap around to the end of the buffer and continue
12851 up to and including the current line, so that the entire buffer is searched.

12852 7. A plus-sign (`'+'`) or hyphen character (`'−'`) followed by a decimal number shall address
12853 the current line plus or minus the number. A plus-sign or hyphen character not followed
12854 by a decimal number shall address the current line plus or minus 1.

12855 Addresses can be followed by zero or more address offsets, optionally <blank>-separated.
12856 Address offsets are constructed as follows:

12857 - A plus-sign or hyphen character followed by a decimal number shall add or subtract,
12858 respectively, the indicated number of lines to or from the address. A plus-sign or hyphen
12859 character not followed by a decimal number shall add or subtract 1 to or from the address.

12860 - A decimal number shall add the indicated number of lines to the address.

12861 It shall not be an error for an intermediate address value to be less than zero or greater than the
12862 last line in the edit buffer. It shall be an error for the final address value to be less than zero or
12863 greater than the last line in the edit buffer. It shall be an error if a search for a BRE fails to find a
12864 matching line.

12865 Commands accept zero, one, or two addresses. If more than the required number of addresses
12866 are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more
12867 than the required number of addresses are provided to a command, the addresses specified first

shall be evaluated and then discarded until the maximum number of valid addresses remain, for the specified command.

Addresses shall be separated from each other by a comma (`','`) or semicolon character (`';'`). In the case of a semicolon separator, the current line (`'.'`) shall be set to the first address, and only then will the second address be calculated. This feature can be used to determine the starting line for forwards and backwards searches; see rules 5. and 6.

Addresses can be omitted on either side of the comma or semicolon separator, in which case the resulting address pairs shall be as follows:

Specified	Resulting
`,`	`1 , $`
`, addr`	`1 ,a ddr`
`addr ,`	`addr , addr`
`;`	`. ; $`
`; addr`	`. ; addr`
`addr ;`	`addr ; addr`

Any <blank> characters included between addresses, address separators, or address offsets shall be ignored.

Commands in ed

In the following list of *ed* commands, the default addresses are shown in parentheses. The number of addresses shown in the default shall be the number expected by the command. The parentheses are not part of the address; they show that the given addresses are the default.

It is generally invalid for more than one command to appear on a line. However, any command (except **e**, **E**, **f**, **q**, **Q**, **r**, **w**, and !) can be suffixed by the letter **l**, **n**, or **p**; in which case, except for the **l**, **n**, and **p** commands, the command shall be executed and then the new current line shall be written as described below under the **l**, **n**, and **p** commands. When an **l**, **n**, or **p** suffix is used with an **l**, **n**, or **p** command, the command shall write to standard output as described below, but it is unspecified whether the suffix writes the current line again in the requested format or whether the suffix has no effect. For example, the **pl** command (base **p** command with an **l** suffix) shall either write just the current line or write it twice—once as specified for **p** and once as specified for **l**. Also, the **g**, **G**, **v**, and **V** commands shall take a command as a parameter.

Each address component can be preceded by zero or more <blank> characters. The command letter can be preceded by zero or more <blank> characters. If a suffix letter (**l**, **n**, or **p**) is given, the application shall ensure that it immediately follows the command.

The **e**, **E**, **f**, **r**, and **w** commands shall take an optional *file* parameter, separated from the command letter by one or more <blank> characters.

If changes have been made in the buffer since the last **w** command that wrote the entire buffer, *ed* shall warn the user if an attempt is made to destroy the editor buffer via the **e** or **q** commands. The *ed* utility shall write the string:

`"?\n"`

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged. If the **e** or **q** command is repeated with no intervening command, it shall take effect.

If a terminal disconnect is detected:

- If the buffer is not empty and has changed since the last write, the *ed* utility shall attempt to write a copy of the buffer to a file named **ed.hup** in the current directory. If this write fails, *ed* shall attempt to write a copy of the buffer to a file name **ed.hup** in the directory named by the *HOME* environment variable. If both these attempts fail, *ed* shall exit without saving the buffer.
- The *ed* utility shall not write the file to the currently remembered path name or return to command mode, and shall terminate with a non-zero exit status.

If an end-of-file is detected on standard input:

- If the *ed* utility is in input mode, *ed* shall terminate input mode and return to command mode. It is unspecified if any partially entered lines (that is, input text without a terminating <newline> character) are discarded from the input text.
- If the *ed* utility is in command mode, it shall act as if a **q** command had been entered.

If the closing delimiter of an RE or of a replacement string (for example, `'/'`) in a **g**, **G**, **s**, **v**, or **V** command would be the last character before a <newline> character, that delimiter can be omitted, in which case the addressed line shall be written. For example, the following pairs of commands are equivalent:

```
s/s1/s2     s/s1/s2/p
g/s1        g/s1/p
?s1         ?s1?
```

If an invalid command is entered, *ed* shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged.

Append Command

Synopsis:

```
(.)a
<text>
.
```

The **a** command shall read the given text and append it after the addressed line; the current line number shall become the address of the last inserted line or, if there were none, the addressed line. Address 0 shall be valid for this command; it shall cause the appended text to be placed at the beginning of the buffer.

Change Command

Synopsis:

```
(.,.)c
<text>
.
```

The **c** command shall delete the addressed lines, then accept input text that replaces these lines; the current line shall be set to the address of the last line input; or, if there were none, at the line after the last line deleted; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

12952 **Delete Command**

12953 *Synopsis*: `(.,.)d`

12954 The **d** command shall delete the addressed lines from the buffer. The address of the line after the
12955 last line deleted shall become the current line number; if the lines deleted were originally at the
12956 end of the buffer, the current line number shall be set to the address of the new last line; if no
12957 lines remain in the buffer, the current line number shall be set to zero.

12958 **Edit Command**

12959 *Synopsis*: `e [`*`file`*`]`

12960 The **e** command shall delete the entire contents of the buffer and then read in the file named by
12961 the path name *file*. The current line number shall be set to the address of the last line of the
12962 buffer. If no path name is given, the currently remembered path name, if any, shall be used (see
12963 the **f** command). The number of bytes read shall be written to standard output, unless the **–s**
12964 option was specified, in the following format:

12965 `"%d\n", <`*`number of bytes read`*`>`

12966 The name *file* shall be remembered for possible use as a default path name in subsequent **e**, **E**, **r**,
12967 and **w** commands. If *file* is replaced by `'!'`, the rest of the line shall be taken to be a shell
12968 command line whose output is to be read. Such a shell command line shall not be remembered
12969 as the current *file*. All marks shall be discarded upon the completion of a successful **e** command.
12970 If the buffer has changed since the last time the entire buffer was written, the user shall be
12971 warned, as described previously.

12972 **Edit Without Checking Command**

12973 *Synopsis*: `E [`*`file`*`]`

12974 The **E** command shall possess all properties and restrictions of the **e** command except that the
12975 editor shall not check to see whether any changes have been made to the buffer since the last **w**
12976 command.

12977 **File Name Command**

12978 *Synopsis*: `f [`*`file`*`]`

12979 If *file* is given, the **f** command shall change the currently remembered path name to *file*; whether
12980 the name is changed or not, it shall then write the (possibly new) currently remembered path
12981 name to the standard output in the following format:

12982 `"%s\n", <`*`pathname`*`>`

12983 The current line number shall be unchanged.

12984 **Global Command**

12985 *Synopsis*: `(1,$)g/`*`RE`*`/`*`command list`*

12986 In the **g** command, the first step shall be to mark every line that matches the given *RE*. Then,
12987 going sequentially from the beginning of the file to the end of the file, the given *command list*
12988 shall be executed for each marked line, with the current line number set to the address of that
12989 line. Any line modified by the *command list* shall be unmarked. When the **g** command completes,
12990 the current line number shall have the value assigned by the last command in the *command list*.
12991 If there were no matching lines, the current line number shall not be changed. A single command
12992 or the first of a list of commands shall appear on the same line as the global command. All lines

of a multi-line list except the last line shall be ended with a backslash; the **a**, **i**, and **c** commands and associated input are permitted. The `'.'` terminating input mode can be omitted if it would be the last line of the *command list*. An empty *command list* shall be equivalent to the **p** command. The use of the **g**, **G**, **v**, **V**, and **!** commands in the *command list* produces undefined results. Any character other than <space> or <newline> can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

Interactive Global Command

Synopsis: `(1,$)G/`*RE*`/`

In the **G** command, the first step shall be to mark every line that matches the given *RE*. Then, for every such line, that line shall be written, the current line number shall be set to the address of that line, and any one command (other than one of the **a**, **c**, **i**, **g**, **G**, **v**, and **V** commands) shall be read and executed. A <newline> character shall act as a null command (causing no action to be taken on the current line); an `'&'` shall cause the re-execution of the most recent non-null command executed within the current invocation of **G**. Note that the commands input as part of the execution of the **G** command can address and affect any lines in the buffer. The final value of the current line number shall be the value set by the last command successfully executed. (Note that the last command successfully executed shall be the **G** command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number shall not be changed. The **G** command can be terminated by a SIGINT signal. Any character other than <space> or <newline> can be used instead of a slash to delimit the *RE* and the replacement. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

Help Command

Synopsis: `h`

The **h** command shall write a short message to standard output that explains the reason for the most recent `'?'` notification. The current line number shall be unchanged.

Help-Mode Command

Synopsis: `H`

The **H** command shall cause *ed* to enter a mode in which help messages (see the **h** command) shall be written to standard output for all subsequent `'?'` notifications. The **H** command alternatively shall turn this mode on and off; it is initially off. If the help-mode is being turned on, the **H** command also explains the previous `'?'` notification, if there was one. The current line number shall be unchanged.

Insert Command

Synopsis:
```
(.)i
<text>
.
```

The **i** command shall insert the given text before the addressed line; the current line is set to the last inserted line or, if there was none, to the addressed line. This command differs from the **a** command only in the placement of the input text. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

13035 **Join Command**

13036 *Synopsis*: `(.,.+1)j`

13037 The **j** command shall join contiguous lines by removing the appropriate <newline> characters. If
13038 exactly one address is given, this command shall do nothing. If lines are joined, the current line
13039 number shall be set to the address of the joined line; otherwise, the current line number shall be
13040 unchanged.

13041 **Mark Command**

13042 *Synopsis*: `(.)k`*x*

13043 The **k** command shall mark the addressed line with name *x*, which the application shall ensure is
13044 a lowercase letter from the portable character set. The address `"'x"` shall then refer to this line;
13045 the current line number shall be unchanged.

13046 **List Command**

13047 *Synopsis*: `(.,.)l`

13048 The **l** command shall write to standard output the addressed lines in a visually unambiguous |
13049 form. The characters listed in the Base Definitions volume of IEEE Std. 1003.1-200x, Table 5-1, |
13050 Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`, `'\t'`, `'\v'`) shall |
13051 be written as the corresponding escape sequence; the `'\n'` in that table is not applicable. Non-
13052 printable characters not in the table shall be written as one three-digit octal number (with a
13053 preceding backslash character) for each byte in the character (most significant byte first). If the
13054 size of a byte on the system is greater than nine bits, the format used for non-printable characters
13055 is implementation-defined. |

13056 Long lines shall be folded, with the point of folding indicated by writing backslash/<newline>
13057 character; the length at which folding occurs is unspecified, but should be appropriate for the
13058 output device. The end of each line shall be marked with a `'$'`, and `'$'` characters within the
13059 text shall be written with a preceding backslash. An **l** command can be appended to any other
13060 command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. The current line number shall be set to the address of
13061 the last line written.

13062 **Move Command**

13063 *Synopsis*: `(.,.)m`*address*

13064 The **m** command shall reposition the addressed lines after the line addressed by *address*.
13065 Address 0 shall be valid for *address* and cause the addressed lines to be moved to the beginning
13066 of the buffer. It shall be an error if address *address* falls within the range of moved lines. The
13067 current line number shall be set to the address of the last line moved.

13068 **Number Command**

13069 *Synopsis*: `(.,.)n`

13070 The **n** command shall write to standard output the addressed lines, preceding each line by its
13071 line number and a <tab> character; the current line number shall be set to the address of the last
13072 line written. The **n** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

13073 **Print Command**

13074 *Synopsis*: `(.,.)p`

13075 The **p** command shall write to standard output the addressed lines; the current line number shall
13076 be set to the address of the last line written. The **p** command can be appended to any command
13077 other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

13078 **Prompt Command**

13079 *Synopsis*: `P`

13080 The **P** command shall cause *ed* to prompt with an asterisk (`'*'`) (or *string*, if **–p** is specified) for
13081 all subsequent commands. The **P** command alternatively shall turn this mode on and off; it shall
13082 be initially on if the **–p** option is specified; otherwise, off. The current line number shall be
13083 unchanged.

13084 **Quit Command**

13085 *Synopsis*: `q`

13086 The **q** command shall cause *ed* to exit. If the buffer has changed since the last time the entire
13087 buffer was written, the user shall be warned, as described previously.

13088 **Quit Without Checking Command**

13089 *Synopsis*: `Q`

13090 The **Q** command shall cause *ed* to exit without checking whether changes have been made in the
13091 buffer since the last **w** command.

13092 **Read Command**

13093 *Synopsis*: `($)r [`*`file`*`]`

13094 The **r** command shall read in the file named by the path name *file* and append it after the
13095 addressed line. If no *file* argument is given, the currently remembered path name, if any, shall be
13096 used (see the **e** and **f** commands). The currently remembered path name shall not be changed
13097 unless there is no remembered path name. Address 0 shall be valid for **r** and shall cause the file
13098 to be read at the beginning of the buffer. If the read is successful, and **–s** was not specified, the
13099 number of bytes read shall be written to standard output in the following format:

13100 `"%d\n", <`*`number of bytes read`*`>`

13101 The current line number shall be set to the address of the last line read in. If *file* is replaced by
13102 `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read.
13103 Such a shell command line shall not be remembered as the current path name.

13104 **Substitute Command**

13105 *Synopsis*: `(.,.)s/`*`RE`*`/`*`replacement`*`/`*`flags`*

13106 The **s** command shall search each addressed line for an occurrence of the specified RE and
13107 replace either the first or all (non-overlapped) matched strings with the *replacement*; see the
13108 following description of the **g** suffix. It is an error if the substitution fails on every addressed
13109 line. Any character other than <space> or <newline> can be used instead of a slash to delimit the
13110 *RE* and the replacement. Within the *RE*, the *RE* delimiter itself can be used as a literal character if
13111 it is preceded by a backslash. The current line shall be set to the address of the last line on which
13112 a substitution occurred.

An ampersand ('&') appearing in the *replacement* shall be replaced by the string matching the RE on the current line. The special meaning of '&' in this context can be suppressed by preceding it by backslash. As a more general feature, the characters '\n', where *n* is a digit, shall be replaced by the text matched by the corresponding back-reference expression. When the character '%' is the only character in the *replacement*, the *replacement* used in the most recent substitute command shall be used as the *replacement* in the current substitute command; if there was no previous substitute command, the use of '%' in this manner shall be an error. The '%' shall lose its special meaning when it is in a replacement string of more than one character or is preceded by a backslash. For each backslash ('\') encountered in scanning *replacement* from beginning to end, the following character shall lose its special meaning (if any). It is unspecified what special meaning is given to any character other than '&', '\', '%', or digits.

A line can be split by substituting a <newline> character into it. The application shall ensure it escapes the <newline> character in the *replacement* by preceding it by backslash. Such substitution cannot be done as part of a **g** or **v** *command list*. The current line number shall be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number shall be unchanged. If a line is split, a substitution shall be considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces.

The application shall ensure that the value of *flags* is zero or more of:

count Substitute for the *count*th occurrence only of the *RE* found on each addressed line.

g Globally substitute for all non-overlapping instances of the *RE* rather than just the first one. If both **g** and *count* are specified, the results are unspecified.

l Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **l** command.

n Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **n** command.

p Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the **p** command.

Copy Command

Synopsis: `(.,.)t`*address*

The **t** command shall be equivalent to the **m** command, except that a copy of the addressed lines shall be placed after address *address* (which can be 0); the current line number shall be set to the address of the last line added.

Undo Command

Synopsis: `u`

The **u** command shall nullify the effect of the most recent command that modified anything in the buffer, namely the most recent **a**, **c**, **d**, **g**, **i**, **j**, **m**, **r**, **s**, **t**, **u**, **v**, **G**, or **V** command. All changes made to the buffer by a **g**, **G**, **v**, or **V** global command shall be undone as a single change; if no changes were made by the global command (such as with **g**/*RE*/**p**), the **u** command shall have no effect. The current line number shall be set to the value it had immediately before the command being undone started.

13155 **Global Non-Matched Command**

13156 *Synopsis*: `(1,$)v/`*`RE`*`/`*`command list`*

13157 This command shall be equivalent to the global command **g** except that the lines that are marked
13158 during the first step shall be those that do not match the *RE*.

13159 **Interactive Global Not-Matched Command**

13160 *Synopsis*: `(1,$)V/`*`RE`*`/`

13161 This command shall be equivalent to the interactive global command **G** except that the lines that
13162 are marked during the first step shall be those that do not match the *RE*.

13163 **Write Command**

13164 *Synopsis*: `(1,$)w [`*`file`*`]`

13165 The **w** command shall write the addressed lines into the file named by the path name *file*. The
13166 command shall create the file, if it does not exist, or shall replace the contents of the existing file.
13167 The currently remembered path name shall not be changed unless there is no remembered path
13168 name. If no path name is given, the currently remembered path name, if any, shall be used (see
13169 the **e** and **f** commands); the current line number shall be unchanged. If the command is
13170 successful, the number of bytes written shall be written to standard output, unless the **–s** option
13171 was specified, in the following format:

13172 `"%d\n", <`*`number of bytes written`*`>`

13173 If *file* begins with `'!'`, the rest of the line shall be taken to be a shell command line whose
13174 standard input shall be the addressed lines. Such a shell command line shall not be remembered
13175 as the current path name. This usage of the write command with `'!'` shall not be considered as
13176 a ‘‘last **w** command that wrote the entire buffer’’, as described previously; thus, this alone shall
13177 not prevent the warning to the user if an attempt is made to destroy the editor buffer via the **e** or
13178 **q** commands.

13179 **Line Number Command**

13180 *Synopsis*: `($)=`

13181 The line number of the addressed line shall be written to standard output in the following
13182 format:

13183 `"%d\n", <`*`line number`*`>`

13184 The current line number shall be unchanged by this command.

13185 **Shell Escape Command**

13186 *Synopsis*: `!`*`command`*

13187 The remainder of the line after the `'!'` shall be sent to the command interpreter to be
13188 interpreted as a shell command line. Within the text of that shell command line, the unescaped
13189 character `'%'` shall be replaced with the remembered path name; if a `'!'` appears as the first
13190 character of the command, it shall be replaced with the text of the previous shell command
13191 executed via `'!'`. Thus, `"!!"` shall repeat the previous !*command*. If any replacements of `'%'` or
13192 `'!'` are performed, the modified line shall be written to the standard output before *command* is
13193 executed. The `'!'` command shall write:

13194 `"!\n"`

13195 to standard output upon completion, unless the –**s** option is specified. The current line number
13196 shall be unchanged.

13197 **Null Command**

13198 *Synopsis*: `(.+1)`

13199 An address alone on a line shall cause the addressed line to be written. A <newline> character
13200 alone shall be equivalent to `"+1p"`. The current line number shall be set to the address of the
13201 written line.

13202 **EXIT STATUS**

13203 The following exit values shall be returned:

13204 0 Successful completion without any file or command errors.

13205 >0 An error occurred.

13206 **CONSEQUENCES OF ERRORS**

13207 When an error in the input script is encountered, or when an error is detected that is a
13208 consequence of the data (not) present in the file or due to an external condition such as a read or
13209 write error:

13210 • If the standard input is a terminal device file, all input shall be flushed, and a new command
13211 read.

13212 • If the standard input is a regular file, *ed* shall terminate with a non-zero exit status.

13213 **APPLICATION USAGE**

13214 Because of the extremely terse nature of the default error messages, the prudent script writer
13215 begins the *ed* input commands with an **H** command, so that if any errors do occur at least some
13216 clue as to the cause is made available.

13217 In previous versions, an obsolescent – option was described. This is no longer specified.
13218 Applications should use the –**s** option. Using – as a *file* operand now produces unspecified
13219 results. This allows implementations to continue to support the former required behavior.

13220 **EXAMPLES**

13221 None.

13222 **RATIONALE**

13223 The initial description of this utility was adapted from the SVID. It contains some features not
13224 found in Version 7 or BSD-derived systems. Some of the differences between the POSIX and
13225 BSD *ed* utilities include, but need not be limited to:

13226 • The BSD – option does not suppress the `'!'` prompt after a **!** command.

13227 • BSD does not support the special meanings of the `'%'` and `'!'` characters within a **!**
13228 command.

13229 • BSD does not support the *addresses* `';'` and `','`.

13230 • BSD allows the command/suffix pairs **pp**, **ll**, and so on, which are unspecified in this volume
13231 of IEEE Std. 1003.1-200x.

13232 • BSD does not support the `'!'` character part of the **e**, **r**, or **w** commands.

13233 • A failed **g** command in BSD sets the line number to the last line searched if there are no
13234 matches.

13235 • BSD does not default the *command list* to the **p** command.

- BSD does not support the **G**, **h**, **H**, **n**, or **V** commands.
- On BSD, if there is no inserted text, the insert command changes the current line to the referenced line −1; that is, the line before the specified line.
- On BSD, the *join* command with only a single address changes the current line to that address.
- BSD does not support the **P** command; moreover, in BSD it is synonymous with the **p** command.
- BSD does not support the *undo* of the commands **j**, **m**, **r**, **s**, or **t**.
- The Version 7 *ed* command **W**, and the BSD *ed* commands **W**, **wq**, and **z** are not present in this volume of IEEE Std. 1003.1-200x.

The **−s** option was added to allow the functionality of the now withdrawn − option in a manner compatible with the Utility Syntax Guidelines.

In early proposals there was a limit, {ED_FILE_MAX}, that described the historical limitations of some *ed* utilities in their handling of large files; some of these have had problems with files larger than 100 000 bytes. It was this limitation that prompted much of the desire to include a *split* command in this volume of IEEE Std. 1003.1-200x. Since this limit was removed, this volume of IEEE Std. 1003.1-200x requires that implementations document the file size limits imposed by *ed* in the conformance document. The limit {ED_LINE_MAX} was also removed; therefore, the global limit {LINE_MAX} is used for input and output lines.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method. On video display terminals, the overstrike is ambiguous because most terminals simply replace overstruck characters, making the **l** format not useful for its intended purpose of unambiguously understanding the content of the line. The historical backslash escapes were also ambiguous. (The string `"a\0011"` could represent a line containing those six characters or a line containing the three characters `'a'`, a byte with a binary value of 1, and a 1.) In the format required here, a backslash appearing in the line is written as `"\\"` so that the output is truly unambiguous. The method of marking the ends of lines was adopted from the *ex* editor and is required for any line ending in <space>s; the `'$'` is placed on all lines so that a real `'$'` at the end of a line cannot be misinterpreted.

Systems with bytes too large to fit into three octal digits must devise other means of displaying non-printable characters. Consideration was given to requiring that the number of octal digits be large enough to hold a byte, but this seemed to be too confusing for applications on the vast majority of systems where three digits are adequate. It would be theoretically possible for the application to use the *getconf* utility to find out the CHAR_BIT value and deal with such an algorithm; however, there is really no portable way that an application can use the octal values of the bytes across various coded character sets, so the additional specification was not worthwhile.

The description of how a NUL is written was removed. The NUL character cannot be in text files, and this volume of IEEE Std. 1003.1-200x should not dictate behavior in the case of undefined, erroneous input.

Unlike some of the other editing utilities, the file names accepted by the **E**, **e**, **R**, and **r** commands are not patterns.

Early proposals stated that the **−p** option worked only when standard input was associated with a terminal device. This has been changed to conform to historical implementations, thereby allowing applications to interpose themselves between a user and the *ed* utility.

The form of the substitute command that uses the **n** suffix was limited in some historical documentation (where this was described incorrectly as ‘‘backreferencing’’). This limit has been omitted because there is no reason an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/x/X/2 047** should be able to substitute the 2 047th occurrence of **x** on a line.

The use of printing commands with printing suffixes (such as **pn**, **lp**, and so on) was made unspecified because BSD-based systems allow this, whereas System V does not.

Some BSD-based systems exit immediately upon receipt of end-of-file if all of the lines in the file have been deleted. Since this volume of IEEE Std. 1003.1-200x refers to the **q** command in this instance, such behavior is not allowed.

Some historical implementations returned exit status zero even if command errors had occurred; this is not allowed by this volume of IEEE Std. 1003.1-200x.

Some historical implementations contained a bug that allowed a single period to be entered in input mode as <backslash> <period> <newline>. This is not allowed by the *ed* because there is no description of escaping any of the characters in input mode; backslashes are entered into the buffer exactly as typed. The typical method of entering a single period has been to precede it with another character and then use the substitute command to delete that character.

It is difficult under some modes of some versions of historical operating system terminal drivers to distinguish between an end-of-file condition and terminal disconnect. The ISO POSIX-2 standard does not require implementations to distinguish between the two situations, which permits historical implementations of the *ed* utility on historical platforms to conform. Implementations are encouraged to distinguish between the two, if possible, and take appropriate action on terminal disconnect.

Historically, *ed* accepted a zero address for the **a** and **r** commands in order to insert text at the start of the edit buffer. When the buffer was empty the command **.=** returned zero. IEEE Std. 1003.1-200x requires conformance to historical practice.

For consistency with the **a** and **r** commands and better user functionality, the **i** and **c** commands must also accept an address of 0, in which case 0*i* is treated as 1*i* and likewise for the **c** command.

All of the following are valid addresses:

`+++`	Three lines after the current line.
`/pattern/-`	One line before the next occurrence of pattern.
`-2`	Two lines before the current line.
`3 ---- 2`	Line one (note the intermediate negative address).
`1 2 3`	Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command `"3;/foo/;+2p"` will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address `"3;"` must still be evaluated before being discarded, because the search origin for the `"/foo/"` command depends on this.

Historically, *ed* disallowed address chains, as discussed above, consisting solely of comma or semicolon separators; for example, `",,,"` or `";;;"` were considered an error. For consistency of address specification, this restriction is removed. The following table lists some of the address

forms now possible:

Address	Addr1	Addr2	Status	Comment
`7,`	`7`	`7`	Historical	
`7,5,`	`5`	`5`	Historical	
`7,5,9`	`5`	`9`	Historical	
`7,9`	`7`	`9`	Historical	
`7,+`	`7`	`8`	Historical	
`,`	`1`	`$`	Historical	
`,7`	`1`	`7`	Extension	
`,,`	`$`	`$`	Extension	
`,;`	`$`	`$`	Extension	
`7;`	`7`	`7`	Historical	
`7;5;`	`5`	`5`	Historical	
`7;5;9`	`5`	`9`	Historical	
`7;5,9`	`5`	`9`	Historical	
`7;$;4`	`$`	`4`	Historical	Valid, but erroneous.
`7;9`	`7`	`9`	Historical	
`7;+`	`7`	`8`	Historical	
`;`	`.`	`$`	Historical	
`;7`	`.`	`7`	Extension	
`;;`	`$`	`$`	Extension	
`;,`	`$`	`$`	Extension	

Historically, values could be added to addresses by including them after one or more <blank> characters; for example, `"3 – 5p"` wrote the seventh line of the file, and `"/foo/ 5"` was the same as `"5 /foo/"`. However, only absolute values could be added; for example, `"5 /foo/"` was an error. IEEE Std. 1003.1-200x requires conformance to historical practice.

Historically, *ed* accepted the `'^'` character as an address, in which case it was identical to the hyphen character. IEEE Std. 1003.1-200x does not require or prohibit this behavior.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO/IEC 9945-2:1993 standard.

Issue 5

In the OPTIONS section, the meaning of **–s** and – is clarified.

Second FUTURE DIRECTION added.

Issue 6

The obsolescent single-minus form has been removed.

A second APPLICATION USAGE note has been added.

The Open Group corrigenda item U025/2 has been applied, correcting the description of the Edit section.

The *ed* utility is updated to align with the IEEE P1003.2b draft standard. This includes addition of the treatment of the SIGQUIT signal, changes to *ed* addressing, changes to processing when end-of-file is detected and when terminal disconnect is detected.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

13374 **NAME**

13375 env — set the environment for command invocation

13376 **SYNOPSIS**

13377 `env [–i][name=value]... [utility [argument...]]`

13378 **DESCRIPTION**

13379 The *env* utility shall obtain the current environment, modify it according to its arguments, then
13380 invoke the utility named by the *utility* operand with the modified environment.

13381 Optional arguments shall be passed to *utility*.

13382 If no *utility* operand is specified, the resulting environment shall be written to the standard
13383 output, with one *name=value* pair per line.

13384 **OPTIONS**

13385 The *env* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
13386 12.2, Utility Syntax Guidelines.

13387 The following options shall be supported:

13388 **–i** Invoke *utility* with exactly the environment specified by the arguments; the
13389 inherited environment shall be ignored completely.

13390 **OPERANDS**

13391 The following operands shall be supported:

13392 *name=value* Arguments of the form *name=value* shall modify the execution environment, and
13393 shall be placed into the inherited environment before the *utility* is invoked.

13394 *utility* The name of the utility to be invoked. If the *utility* operand names any of the
13395 special built-in utilities in Section 2.15 (on page 2276), the results are undefined.

13396 *argument* A string to pass as an argument for the invoked utility.

13397 **STDIN**

13398 Not used.

13399 **INPUT FILES**

13400 None.

13401 **ENVIRONMENT VARIABLES**

13402 The following environment variables shall affect the execution of *env*:

13403 *LANG* Provide a default value for the internationalization variables that are unset or null.
13404 If *LANG* is unset or null, the corresponding value from the implementation-
13405 defined default locale shall be used. If any of the internationalization variables
13406 contains an invalid setting, the utility shall behave as if none of the variables had
13407 been defined.

13408 *LC_ALL* If set to a non-empty string value, override the values of all the other
13409 internationalization variables.

13410 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
13411 characters (for example, single-byte as opposed to multi-byte characters in
13412 arguments).

13413 *LC_MESSAGES*

13414 Determine the locale that should be used to affect the format and contents of
13415 diagnostic messages written to standard error.

13416 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

13417 *PATH* Determine the location of the *utility*, as described in the Base Definitions volume of
13418 IEEE Std. 1003.1-200x, Chapter 8, Environment Variables. If *PATH* is specified as a
13419 *name*=*value* operand to *env*, the *value* given shall be used in the search for *utility*.

13420 **ASYNCHRONOUS EVENTS**
13421 Default.

13422 **STDOUT**
13423 If no *utility* operand is specified, each *name*=*value* pair in the resulting environment shall be
13424 written in the form:

13425 `"%s=%s\n", <name>, <value>`

13426 If the *utility* operand is specified, the *env* utility shall not write to standard output.

13427 **STDERR**
13428 Used only for diagnostic messages.

13429 **OUTPUT FILES**
13430 None.

13431 **EXTENDED DESCRIPTION**
13432 None.

13433 **EXIT STATUS**
13434 If the *utility* utility is invoked, the exit status of *env* shall be the exit status of *utility*; otherwise,
13435 the *env* utility shall exit with one of the following values:

13436 0 The *env* utility completed successfully.

13437 1–125 An error occurred in the *env* utility.

13438 126 The utility specified by *utility* was found but could not be invoked.

13439 127 The utility specified by *utility* could not be found.

13440 **CONSEQUENCES OF ERRORS**
13441 Default.

13442 **APPLICATION USAGE**
13443 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if
13444 an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked
13445 utility exited with an error indication’’. The value 127 was chosen because it is not commonly
13446 used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the
13447 values above 128 can be confused with termination due to receipt of a signal. The value 126 was
13448 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
13449 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
13450 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
13451 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
13452 any other reason.

13453 Historical implementations of the *env* utility use the *execvp*( ) or *execlp*( ) functions defined in the
13454 System Interfaces volume of IEEE Std. 1003.1-200x to invoke the specified utility; this provides
13455 better performance and keeps users from having to escape characters with special meaning to
13456 the shell. Therefore, shell functions, special built-ins, and built-ins that are only provided by the
13457 shell are not found.

13458 **EXAMPLES**

13459 The following command:

13460
```
env –i PATH=/mybin mygrep xyz myfile
```

13461 invokes the command *mygrep* with a new *PATH* value as the only entry in its environment. In
13462 this case, *PATH* is used to locate *mygrep*, which then must reside in **/mybin**.

13463 **RATIONALE**

13464 As with all other utilities that invoke other utilities, this volume of IEEE Std. 1003.1-200x only
13465 specifies what *env* does with standard input, standard output, standard error, input files, and
13466 output files. If a utility is executed, it is not constrained by the specification of input and output
13467 by *env*.

13468 The **–i** option was added to allow the functionality of the withdrawn – option in a manner
13469 compatible with the Utility Syntax Guidelines.

13470 Some have suggested that *env* is redundant since the same effect is achieved by:

13471
```
name=value ... utility [ argument ... ]
```

13472 The example is equivalent to *env* when an environment variable is being added to the
13473 environment of the command, but not when the environment is being set to the given value.
13474 The *env* utility also writes out the current environment if invoked without arguments. There is
13475 sufficient functionality beyond what the example provides to justify inclusion of *env*.

13476 **FUTURE DIRECTIONS**

13477 None.

13478 **SEE ALSO**

13479 Section 2.5 (on page 2241)

13480 **CHANGE HISTORY**

13481 First released in Issue 2.

13482 **Issue 4**

13483 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

ex — text editor

SYNOPSIS

UP

```
ex [–rR][–l][–s | –v][–c command]–t tagstring][–w size][file ...]
```

DESCRIPTION

The *ex* utility is a line-oriented text editor. There are two other modes of the editor—open and visual—in which screen-oriented editing is available. This is described more fully by the *ex* **open** and **visual** commands and in *vi*.

This section uses the term *edit buffer* to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

Certain terminals do not have all the capabilities necessary to support the complete *ex* definition, such as the full-screen editing commands (*visual mode* or *open mode*). When these commands cannot be supported on such terminals, this condition shall not produce an error message such as ‘‘not an editor command’’ or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std. 1003.1-200x or report an error describing the terminal-related deficiency.

OPTIONS

The *ex* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–c *command* Specify an initial command to be executed in the first edit buffer loaded from an existing file (see the EXTENDED DESCRIPTION section). Implementations may support more than a single **–c** option. In such implementations, the specified commands shall be executed in the order specified on the command line.

–l (The letter ell.) Set lisp mode; indents appropriately for LISP code; the **()**, **{}**, **[[**, and **]]** commands in visual mode are modified to have meaning for LISP.

–r Recover the named files (see the EXTENDED DESCRIPTION section). Recovery information for a file shall be saved during an editor or system crash (for example, when the editor is terminated by a signal which the editor can catch), or after the use of an *ex* **preserve** command.

A *crash* in this context is an unexpected failure of the system or utility that requires restarting the failed system or utility. A system crash implies that any utilities running at the time also crash. In the case of an editor or system crash, the number of changes to the edit buffer (since the most recent **preserve** command) that will be recovered is unspecified.

If no *file* operands are given and the **–t** option is not specified, all other options, the *EXINIT* variable, and any **.exrc** files shall be ignored; a list of all recoverable files available to the invoking user shall be written, and the editor shall exit normally without further action.

–R Set **readonly** edit option.

–s Prepare *ex* for batch use by taking the following actions:

- Suppress writing prompts and informational (but not diagnostic) messages.
- Ignore the value of *TERM* and any implementation default terminal type and assume the terminal is a type incapable of supporting open or visual modes; see the **visual** command and the description of *vi*.
- Suppress the use of the *EXINIT* environment variable and the reading of any **.exrc** file; see the EXTENDED DESCRIPTION section.
- Suppress autoindentation, ignoring the value of the **autoindent** edit option.

–t *tagstring* Edit the file containing the specified *tagstring*; see *ctags*. The tags feature represented by **–t** *tagstring* and the **tag** command is optional. It shall be provided on any system that also provides a conforming implementation of *ctags*; otherwise, the use of **–t** produces undefined results. On any system, it shall be an error to specify more than a single **–t** option.

–v Begin in visual mode (see *vi*).

–w *size* Set the value of the *window* editor option to *size*.

OPERANDS

The following operand shall be supported:

file A path name of a file to be edited.

STDIN

The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section. The implementation may limit each line of standard input to a length of {LINE_MAX}.

If the standard input is not a terminal device, it shall be as if the **–s** option had been specified.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

INPUT FILES

Input files shall be text files or files that would be text files except for an incomplete last line that is not longer than {LINE_MAX}–1 bytes in length and contains no NUL characters. By default, any incomplete last line shall be treated as if it had a trailing <newline> character. The editing of other forms of files may optionally be allowed by *ex* implementations.

The **.exrc** files and source files shall be text files consisting of *ex* commands; see the EXTENDED DESCRIPTION section.

By default, the editor shall read lines from the files to be edited without interpreting any of those lines as any form of editor command.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ex*:

COLUMNS Override the system-selected horizontal screen size. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

EXINIT Determine a list of *ex* commands that are executed on editor start-up. See the EXTENDED DESCRIPTION section for more details of the initialization phase.

HOME Determine a path name of a directory that shall be searched for an editor start-up file named **.exrc**; see the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the classification of characters as uppercase or lowercase letters, the case conversion of letters, and the detection of word boundaries.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path for the shell command specified in the *ex* editor commands **!**, **shell**, **read**, and **write**, and the open and visual mode command **!**; see the description of command search and execution in Section 2.9.1.1 (on page 2257).

SHELL Determine the preferred command line interpreter for use as the default value of the **shell** edit option.

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

The following term is used in this and following sections to specify command and asynchronous event actions:

complete write
A complete write is a write of the entire contents of the edit buffer to a file of a type other than a terminal device, or the saving of the edit buffer caused by the user executing the *ex* **preserve** command. Writing the contents of the edit buffer to a temporary file that will be removed when the editor exits shall not be considered a complete write.

The following actions shall be taken upon receipt of signals:

SIGINT If the standard input is not a terminal device, *ex* shall not write the file or return to command or text input mode, and shall exit with a non-zero exit status.

Otherwise, if executing an open or visual text input mode command, *ex* in receipt of SIGINT shall behave identically to its receipt of the <ESC> character.

Otherwise:

1. If executing an *ex* text input mode command, all input lines that have been completely entered shall be resolved into the edit buffer, and any partially entered line shall be discarded.
2. If there is a currently executing command, it shall be aborted and a message displayed. Unless otherwise specified by the *ex* or *vi* command descriptions, it is unspecified whether any lines modified by the executing command appear modified, or as they were before being modified by the executing command, in the buffer.

   If the currently executing command was a motion command, its associated command shall be discarded.
3. If in open or visual command mode, the terminal shall be alerted.
4. The editor shall then return to command mode.

SIGCONT The screen shall be refreshed if in open or visual mode.

SIGHUP If the edit buffer has been modified since the last complete write, *ex* shall attempt to save the edit buffer so that it can be recovered later using the **–r** option or the *ex* **recover** command. The editor shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

SIGTERM Refer to SIGHUP.

The action taken for all other signals is unspecified.

STDOUT

The standard output shall be used only for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

The output from *ex* shall be text files.

EXTENDED DESCRIPTION

Only the *ex* mode of the editor is described in this section. See *vi* for additional editing capabilities available in *ex*.

When an error occurs, *ex* shall write a message. If the terminal supports a standout mode (such as inverse video), the message shall be written in standout mode. If the terminal does not support a standout mode, and the edit option **errorbells** is set, an alert action shall precede the error message.

By default, *ex* shall start in command mode, which shall be indicated by a **:** prompt; see the **prompt** command. Text input mode can be entered by the **append**, **insert**, or **change** commands; it can be exited (and command mode re-entered) by typing a period (**'.'**) alone at the beginning of a line.

Initialization in ex and vi

The following symbols are used in this and following sections to specify locations in the edit buffer:

alternate and current path names

Two path names, named *current* and *alternate*, are maintained by the editor. Any *ex* commands that take file names as arguments shall set them as follows:

1. If a *file* argument is specified to the *ex* **edit**, **ex**, or **recover** commands, or if an *ex* **tag** command replaces the contents of the edit buffer.
    a. If the command replaces the contents of the edit buffer, the current path name shall be set to the *file* argument or the file indicated by the tag, and the alternate path name shall be set to the previous value of the current path name.
    b. Otherwise, the alternate path name shall be set to the *file* argument.
2. If a *file* argument is specified to the *ex* **next** command:
    a. If the command replaces the contents of the edit buffer, the current path name shall be set to the first *file* argument, and the alternate path name shall be set to the previous value of the current path name.
3. If a *file* argument is specified to the *ex* **file** command, the current path name shall be set to the *file* argument, and the alternate path name shall be set to the previous value of the current path name.
4. If a *file* argument is specified to the *ex* **read** and **write** commands (that is, when reading or writing a file, and not to the program named by the **shell** edit option), or a *file* argument is specified to the *ex* **xit** command:
    a. If the current path name has no value, the current path name shall be set to the *file* argument.
    b. Otherwise, the alternate path name shall be set to the *file* argument.

If the alternate path name is set to the previous value of the current path name when the current path name had no previous value, then the alternate path name shall have no value as a result.

current line

The line of the edit buffer referenced by the cursor. Each command description specifies the current line after the command has been executed, as the *current line value*. When the edit buffer contains no lines, the current line shall be zero; see **Addressing in ex** (on page 2571).

current column

The current screen column occupied by the cursor. (The columns shall be numbered beginning at 1.) Each command description specifies the current column after the command has been executed, as the *current column* value. This column is an *ideal* column that is remembered over the lifetime of the editor. The actual screen column upon which the cursor rests may be different from the current column; see the cursor positioning discussion in **Command Descriptions in vi** (on page 3201).

set to non-<blank>

A description for a current column value, meaning that the current column shall be set to the last screen column on which is displayed any part of the first non-<blank> character of the line. If the line has no non-<blank> characters, the current column shall be set to the last screen column on which is displayed any part of the last character in the line. If the line is empty, the current column shall be set to column position 1.

The length of lines in the edit buffer may be limited to {LINE_MAX} bytes. In open and visual mode, the length of lines in the edit buffer may be limited to the number of characters that will fit in the display. If either limit is exceeded during editing, an error message shall be written. If either limit is exceeded by a line read in from a file, an error message shall be written and the edit session may be terminated.

If the editor stops running due to any reason other than a user command, and the edit buffer has been modified since the last complete write, it shall be equivalent to a SIGHUP asynchronous event. If the system crashes, it shall be equivalent to a SIGHUP asynchronous event.

During initialization (before the first file is copied into the edit buffer or any user commands from the terminal are processed) the following shall occur:

1. If the environment variable *EXINIT* is set, the editor shall execute the *ex* commands contained in that variable.
2. If the *EXINIT* variable is not set, and all of the following are true:
   a. The *HOME* environment variable is not null and not empty.
   b. The file **.exrc** in the directory referred to by the *HOME* environment variable:
      1. Exists
      2. Is owned by the same user ID as the real user ID of the process or the process has appropriate privileges
      3. Is not writeable by anyone other than the owner

   the editor shall execute the *ex* commands contained in that file.
3. If and only if all the following are true:
   a. The current directory is not referred to by the *HOME* environment variable.
   b. A command in the *EXINIT* environment variable or a command in the **.exrc** file in the directory referred to by the *HOME* environment variable sets the editor option **exrc**.
   c. The **.exrc** file in the current directory:
      1. Exists
      2. Is owned by the same user ID as the real user ID of the process, or by one of a set of implementation-defined user IDs
      3. Is not writeable by anyone other than the owner

   the editor shall attempt to execute the *ex* commands contained in that file.

Lines in any **.exrc** file that contain no characters or only <blank> characters shall be ignored. If any **.exrc** file exists, but is not read for ownership or permission reasons, it shall be an error.

After the *EXINIT* variable and any **.exrc** files are processed, the first file specified by the user shall be edited, as follows:

1. If the user specified the **–t** option, the effect shall be as if the *ex* **tag** command was entered with the specified argument, with the exception that if tag processing does not result in a file to edit, the effect shall be as described in step 3. below.
2. Otherwise, if the user specified any command line *file* arguments, the effect shall be as if the *ex* **edit** command was entered with the first of those arguments as its *file* argument.
3. Otherwise, the effect shall be as if the *ex* **edit** command was entered with a nonexistent file name as its *file* argument. It is unspecified whether this action shall set the current path

name. In an implementation where this action does not set the current path name, any editor command using the current path name shall fail until an editor command sets the current path name.

If the **–r** option was specified the first time a file in the initial argument list or a file specified by the **–t** option is edited, if recovery information has previously been saved about it, that information shall be recovered and the editor shall behave as if the contents of the edit buffer have already been modified. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. If no recovery information about a file is available, an informational message to this effect shall be written, and the edit shall proceed as usual.

If the – option was specified the first time a file that already exists (including a file that might not exist but for which recovery information is available, when the **–r** option is specified) replaces or initializes the contents of the edit buffer, the current line shall be set to the last line of the edit buffer, the current column shall be set to non-<blank>, and the *ex* commands specified with the **–c** option shall be executed. In this case, the current line and current column shall not be set as described for the command associated with the replacement or initialization of the edit buffer contents. However, if the **–t** option or a **tag** command is associated with this action, the **–c** option commands shall be executed and then the movement to the tag shall be performed.

The current argument list shall initially be set to the file names specified by the user on the command line. If no file names are specified by the user, the current argument list shall be empty. If the **–t** option was specified, it is unspecified whether any file name resulting from tag processing shall be prepended to the current argument list. In the case where the file name is added as a prefix to the current argument list, the current argument list reference shall be set to that file name. In the case where the file name is not added as a prefix to the current argument list, the current argument list reference shall logically be located before the first of the file names specified on the command line (for example, a subsequent *ex* **next** command shall edit the first file name from the command line). If the **–t** option was not specified, the current argument list reference shall be to the first of the file names on the command line.

Addressing in ex

Addressing in *ex* relates to the current line and the current column; the address of a line is its 1-based line number, the address of a column is its 1-based count from the beginning of the line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. In each command description, the effect of the command on the current line number and the current column is described.

Addresses are constructed as follows:

1. The character `'.'` (period) shall address the current line.
2. The character `'$'` shall address the last line of the edit buffer.
3. The positive decimal number *n* shall address the *n*th line of the edit buffer.
4. The address `"'x"` refers to the line marked with the mark name character `'x'`, which shall be a lowercase letter from the portable character set or one of the characters `''` or `'`. It shall be an error if the line that was marked is not currently present in the edit buffer or the mark has not been set. Lines can be marked with the *ex* **mark** or **k** commands, or the *vi* **m** command.
5. A regular expression (RE) enclosed by slashes (`'/'`) shall address the first line found by searching forwards from the line following the current line toward the end of the edit

13784 buffer and stopping at the first line containing a string matching the regular expression. As
13785 stated in **Regular Expressions in ex** (on page 2601), an address consisting of a null regular
13786 expression delimited by slashes "//" shall address the next line containing the last regular
13787 expression encountered. In addition, the second slash can be omitted at the end of a
13788 command line. If the **wrapscan** edit option is set, the search shall wrap around to the
13789 beginning of the edit buffer and continue up to and including the current line, so that the
13790 entire edit buffer is searched. Within the regular expression, the sequence "\/" shall
13791 represent a literal slash instead of the regular expression delimiter.

13792 6. A regular expression enclosed in question marks ('?') shall address the first line found by
13793 searching backwards from the line preceding the current line toward the beginning of the
13794 edit buffer and stopping at the first line containing a string matching the regular
13795 expression. The second question mark can be omitted at the end of a command line. If the
13796 **wrapscan** edit option is set, the search shall wrap around from the beginning of the edit
13797 buffer to the end of the edit buffer and continue up to and including the current line, so
13798 that the entire edit buffer is searched. Within the regular expression, the sequence "\?"
13799 shall represent a literal question mark instead of the RE delimiter.

13800 7. A plus sign ('+') or a minus sign ('−') followed by a decimal number shall address the
13801 current line plus or minus the number. A '+' or '−' not followed by a decimal number
13802 shall address the current line plus or minus 1.

13803 Addresses can be followed by zero or more address offsets, optionally <blank> character-
13804 separated. Address offsets are constructed as follows:

13805 1. A '+' or '−' immediately followed by a decimal number shall add (subtract) the
13806 indicated number of lines to (from) the address. A '+' or '−' not followed by a decimal
13807 number shall add (subtract) 1 to (from) the address.

13808 2. A decimal number shall add the indicated number of lines to the address.

13809 It shall not be an error for an intermediate address value to be less than zero or greater than the
13810 last line in the edit buffer. It shall be an error for the final address value to be less than zero or
13811 greater than the last line in the edit buffer.

13812 Commands take zero, one, or two addresses; see the descriptions of *1addr* and *2addr* in
13813 **Command Descriptions in ex** (on page 2578). If more than the required number of addresses
13814 are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more
13815 than the required number of addresses are provided to a command, the addresses specified first
13816 shall be evaluated and then discarded until the maximum number of valid addresses remain.

13817 Addresses shall be separated from each other by a comma (',') or a semicolon (';'). If no
13818 address is specified before or after a comma or semicolon separator, it shall be as if the address
13819 of the current line was specified before or after the separator. In the case of a semicolon
13820 separator, the current line ('.') shall be set to the first address, and only then will the next
13821 address be calculated. This feature can be used to determine the starting line for forwards and
13822 backwards searches (see rules 5. and 6.).

13823 A percent sign ('%') shall be equivalent to entering the two addresses "1,$".

13824 Any delimiting <blank> characters between addresses, address separators, or address offsets
13825 shall be discarded.

Command Line Parsing in ex

The following symbol is used in this and following sections to describe parsing behavior:

escape If a character is referred to as ‘‘backslash escaped’’ or ‘‘<control>-V escaped,’’ it shall mean that the character acquired or lost a special meaning by virtue of being preceded, respectively, by a backslash or <control>-V character. Unless otherwise specified, the escaping character shall be discarded at that time and shall not be further considered for any purpose.

Command-line parsing shall be done in the following steps. For each step, characters already evaluated shall be ignored; that is, the phrase ‘‘leading character’’ refers to the next character that has not yet been evaluated.

1. Leading colon characters shall be skipped.
2. Leading <blank> characters shall be skipped.
3. If the leading character is a double-quote character, the characters up to and including the next non-backslash-escaped <newline> character shall be discarded, and any subsequent characters shall be parsed as a separate command.
4. Leading characters that can be interpreted as addresses shall be evaluated; see **Addressing in ex** (on page 2571).
5. Leading <blank> characters shall be skipped.
6. If the next character is a vertical-line character or a <newline> character:
   a. If the next character is a <newline> character:
      1. If *ex* is in open or visual mode, the current line shall be set to the last address specified, if any.
      2. Otherwise, if the last command was terminated by a vertical-line character, no action shall be taken; for example, the command `"||<newline>"` shall execute two implied commands, not three.
      3. Otherwise, step 6.b. shall apply.
   b. Otherwise, the implied command shall be the **print** command. The last **#**, **p**, and **l** flags specified to any *ex* command shall be remembered and shall apply to this implied command. Executing the *ex* **number**, **print**, or **list** command shall set the remembered flags to **#**, nothing, and **l**, respectively, plus any other flags specified for that execution of the **number**, **print**, or **list** command.

      If *ex* is not currently performing a **global** or **v** command, and no address or count is specified, the current line shall be incremented by 1 before the command is executed. If incrementing the current line would result in an address past the last line in the edit buffer, the command shall fail, and the increment shall not happen.
   c. The <newline> character or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate command.
7. The command name shall be comprised of the next character (if the character is not alphabetic), or the next character and any subsequent alphabetic characters (if the character is alphabetic), with the following exceptions:
   a. Commands that consist of any prefix of the characters in the command name **delete**, followed immediately by any of the characters **l**, **p**, **+**, **–**, or **#** shall be interpreted as a **delete** command, followed by a <blank> character, followed by the characters that

were not part of the prefix of the **delete** command. The maximum number of characters shall be matched to the command name **delete**; for example, `"del"` shall not be treated as `"de"` followed by the flag **l**.

b. Commands that consist of the character **k**, followed by a character that can be used as the name of a mark, shall be equivalent to the mark command followed by a <blank> character, followed by the character that followed the **k**.

c. Commands that consist of the character **s**, followed by characters that could be interpreted as valid options to the **s** command, shall be the equivalent of the **s** command, without any pattern or replacement values, followed by a <blank> character, followed by the characters after the **s**.

8. The command name shall be matched against the possible command names, and a command name that contains a prefix matching the characters specified by the user shall be the executed command. In the case of commands where the characters specified by the user could be ambiguous, the executed command shall be as follows:

a	**append**	**n**	**next**	**t**	**t**
c	**change**	**p**	**print**	**u**	**undo**
ch	**change**	**pr**	**print**	**un**	**undo**
e	**edit**	**r**	**read**	**v**	**v**
m	**move**	**re**	**read**	**w**	**write**
ma	**mark**	**s**	**s**		

Implementation extensions with names causing similar ambiguities shall not be checked for a match until all possible matches for commands specified by IEEE Std. 1003.1-200x have been checked.

9. If the command is a **!** command, or if the command is a **read** command followed by zero or more <blank> characters and a **!**, or if the command is a **write** command followed by one or more <blank> characters and a **!**, the rest of the command shall include all characters up to a non-backslash-escaped <newline> character. The <newline> character shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

10. Otherwise, if the command is an **edit**, **ex**, or **next** command, or a **visual** command while in open or visual mode, the next part of the command shall be parsed as follows:

a. Any `'!'` character immediately following the command shall be skipped and be part of the command.

b. Any leading <blank> characters shall be skipped and be part of the command.

c. If the next character is a `'+'`, characters up to the first non-backslash-escaped <newline> character or non-backslash-escaped <blank> character shall be skipped and be part of the command.

d. The rest of the command shall be determined by the steps specified in paragraph 12.

11. Otherwise, if the command is a **global**, **open**, **s**, or **v** command, the next part of the command shall be parsed as follows:

a. Any leading <blank> characters shall be skipped and be part of the command.

b. If the next character is not an alphanumeric, double-quote, <newline>, backslash, or vertical-line character:

1. The next character shall be used as a command delimiter.

2. If the command is a **global**, **open**, or **v** command, characters up to the first non-backslash-escaped <newline> character, or first non-backslash-escaped delimiter character, shall be skipped and be part of the command.

3. If the command is an **s** command, characters up to the first non-backslash-escaped <newline> character, or second non-backslash-escaped delimiter character, shall be skipped and be part of the command.

c. If the command is a **global** or **v** command, characters up to the first non-backslash-escaped <newline> character shall be skipped and be part of the command.

d. Otherwise, the rest of the command shall be determined by the steps specified in paragraph 12.

12. Otherwise:

a. If the command was a **map**, **unmap**, **abbreviate**, or **unabbreviate** command, characters up to the first non-<control>-V-escaped <newline>, vertical-line, or double-quote character shall be skipped and be part of the command.

b. Otherwise, characters up to the first non-backslash-escaped <newline>, vertical-line, or double-quote character shall be skipped and be part of the command.

c. If the command was an **append**, **change**, or **insert** command, and the step 12.b. ended at a vertical-line character, any subsequent characters, up to the next non-backslash-escaped <newline> character shall be used as input text to the command.

d. If the command was ended by a double-quote character, all subsequent characters, up to the next non-backslash-escaped <newline> character, shall be discarded.

e. The terminating <newline> or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

Command arguments shall be parsed as described by the Synopsis and Description of each individual *ex* command. This parsing shall not be <blank> character-sensitive, except for the **!** argument, which must follow the command name without intervening <blank> characters, and where it would otherwise be ambiguous. For example, *count* and *flag* arguments need not be <blank> character separated because `"d22p"` is not ambiguous, but *file* arguments to the *ex* **next** command must be separated by one or more <blank> characters. Any <blank> character in command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands can be <control>-V-escaped, in which case the <blank> character shall not be used as an argument delimiter. Any <blank> character in the command argument for any other command can be backslash-escaped, in which case that <blank> character shall not be used as an argument delimiter.

Within command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands, any character can be <control>-V-escaped. All such escaped characters shall be treated literally and shall have no special meaning. Within command arguments for all other *ex* commands that are not regular expressions or replacement strings, any character that would otherwise have a special meaning can be backslash-escaped. Escaped characters shall be treated literally, without special meaning as shell expansion characters or `'!'`, `'%'`, and `'#'` expansion characters. See **Regular Expressions in ex** (on page 2601) and **Replacement Strings in ex** (on page 2602) for descriptions of command arguments that are regular expressions or replacement strings.

Non-backslash-escaped `'%'` characters appearing in *file* arguments to any *ex* command shall be replaced by the current path name; unescaped `'#'` characters shall be replaced by the alternate path name. It shall be an error if `'%'` or `'#'` characters appear unescaped in an argument and their corresponding values are not set.

13959 Non-backslash-escaped '!' characters in the arguments to either the *ex* **!** command or the open
13960 and visual mode **!** command, or in the arguments to the *ex* **read** command, where the first non-
13961 <blank> character after the command name is a '!' character, or in the arguments to the *ex*
13962 **write** command where the command name is followed by one or more <blank> characters and
13963 the first non-<blank> character after the command name is a '!' character, shall be replaced
13964 with the arguments to the last of those three commands as they appeared after all unescaped
13965 '%', '#', and '!' characters were replaced. It shall be an error if '!' characters appear
13966 unescaped in one of these commands and there has been no previous execution of one of these
13967 commands.

13968 If an error occurs during the parsing or execution of an *ex* command:

13969 • An informational message to this effect shall be written. Execution of the *ex* command shall
13970 stop, and the cursor (for example, the current line and column) shall not be further modified.

13971 • If the *ex* command resulted from a map expansion, all characters from that map expansion
13972 shall be discarded, except as otherwise specified by the **map** command.

13973 • Otherwise, if the *ex* command resulted from the processing of an *EXINIT* environment
13974 variable, a **.exrc** file, a **:source** command, a **–c** option, or a **+***command* specified to an *ex* **edit**,
13975 **ex**, **next**, or **visual** command, no further commands from the source of the commands shall
13976 be executed.

13977 • Otherwise, if the *ex* command resulted from the execution of a buffer or a **global** or **v**
13978 command, no further commands caused by the execution of the buffer or the **global** or **v**
13979 command shall be executed.

13980 • Otherwise, if the *ex* command was not terminated by a <newline> character, all characters up
13981 to and including the next non-backslash-escaped <newline> character shall be discarded.

13982 **Input Editing in ex**

13983 The following symbols are used in this and following sections to specify command actions.

13984 *word* In the POSIX locale, a word consists of a maximal sequence of letters, digits, and
13985 underscores, delimited at both ends by characters other than letters, digits, or
13986 underscores, or by the beginning or end of a line or the edit buffer.

13987 When accepting input characters from the user, in either *ex* command mode or *ex* text input
13988 mode, *ex* shall enable canonical mode input processing, as defined in the System Interfaces
13989 volume of IEEE Std. 1003.1-200x.

13990 If in *ex* text input mode:

13991 1. If the **number** edit option is set, *ex* shall prompt for input using the line number that would
13992 be assigned to the line if it is entered, in the format specified for the *ex* **number** command.

13993 2. If the **autoindent** edit option is set, *ex* shall prompt for input using **autoindent** characters,
13994 as described by the **autoindent** edit option. **autoindent** characters shall follow the line
13995 number, if any.

13996 If in *ex* command mode:

13997 1. If the **prompt** edit option is set, input shall be prompted for using a single ':' character;
13998 otherwise, there shall be no prompt.

13999 The input characters in the following sections shall have the following effects on the input line.

14000 **Scroll**

14001 *Synopsis*: `eof`

14002 See the description of the *stty eof* character in *stty*.

14003 If in *ex* command mode:

14004 If the *eof* character is the first character entered on the line, the line shall be evaluated as if it
14005 contained two characters: a <control>-D and a <newline> character.

14006 Otherwise, the *eof* character shall have no special meaning.

14007 If in *ex* text input mode:

14008 If the cursor follows an **autoindent** character, the **autoindent** characters in the line shall be
14009 modified so that a part of the next text input character will be displayed on the first column
14010 in the line after the previous **shiftwidth** edit option column boundary, and the user shall be
14011 prompted again for input for the same line.

14012 Otherwise, if the cursor follows a `'0'`, which follows an **autoindent** character, and the `'0'`
14013 was the previous text input character, the `'0'` and all **autoindent** characters in the line shall
14014 be discarded, and the user shall be prompted again for input for the same line.

14015 Otherwise, if the cursor follows a `'^'`, which follows an **autoindent** character, and the `'^'`
14016 was the previous text input character, the `'^'` and all **autoindent** characters in the line shall
14017 be discarded, and the user shall be prompted again for input for the same line. In addition,
14018 the **autoindent** level for the next input line shall be derived from the same line from which
14019 the **autoindent** level for the current input line was derived.

14020 Otherwise, if there are no **autoindent** or text input characters in the line, the *eof* character
14021 shall be discarded.

14022 Otherwise, the *eof* character shall have no special meaning.

14023 **<newline>**

14024 *Synopsis*: `<newline>`
14025 `<control>-J`

14026 If in *ex* command mode:

14027 Cause the command line to be parsed; <control>-J shall be mapped to the <newline>
14028 character for this purpose.

14029 If in *ex* text input mode:

14030 Terminate the current line. If there are no characters other than **autoindent** characters on the
14031 line, all characters on the line shall be discarded.

14032 Prompt for text input on a new line after the current line. If the **autoindent** edit option is set,
14033 an appropriate number of **autoindent** characters shall be added as a prefix to the line as
14034 described by the *ex* **autoindent** edit option.

<backslash>

Synopsis: `<backslash>`

Allow the entry of a subsequent <newline> or <control>-J as a literal character, removing any special meaning that it may have to the editor during text input mode. The backslash character shall be retained and evaluated when the command line is parsed, or retained and included when the input text becomes part of the edit buffer.

<control>-V

Synopsis: `<control>-V`

Allow the entry of any subsequent character as a literal character, removing any special meaning that it may have to the editor during text input mode. The <control>-V character shall be discarded before the command line is parsed or the input text becomes part of the edit buffer.

If the ''literal next'' functionality is performed by the underlying system, it is implementation-defined whether a character other than <control>-V performs this function.

<control>-W

Synopsis: `<control>-W`

Discard the <control>-W, and the word previous to it in the input line, including any <blank> characters following the word and preceding the <control>-W. If the ''word erase'' functionality is performed by the underlying system, it is implementation-defined whether a character other than <control>-W performs this function.

Command Descriptions in ex

The following symbols are used in this section to represent command modifiers. Some of these modifiers can be omitted, in which case the specified defaults shall be used.

1addr A single line address, given in any of the forms described in **Addressing in ex** (on page 2571); the default shall be the current line (`'.'`), unless otherwise specified.

If the line address is zero, it shall be an error, unless otherwise specified in the following command descriptions.

If the edit buffer is empty, and the address is specified with a command other than **=**, **append**, **insert**, **open**, **put**, **read**, or **visual**, or the address is not zero, it shall be an error.

2addr Two addresses specifying an inclusive range of lines. If no addresses are specified, the default for *2addr* shall be the current line only (`".,."`), unless otherwise specified in the following command descriptions. If one address is specified, *2addr* shall specify that line only, unless otherwise specified in the following command descriptions.

It shall be an error if the first address is greater than the second address.

If the edit buffer is empty, and the two addresses are specified with a command other than the **!**, **write**, **wq**, or **xit** commands, or either address is not zero, it shall be an error.

count A positive decimal number. If *count* is specified, it shall be equivalent to specifying an additional address to the command, unless otherwise specified by the following command descriptions. The additional address shall be equal to the last address specified to the command (either explicitly or by default) plus *count*−1.

If this would result in an address greater than the last line of the edit buffer, it shall be corrected to equal the last line of the edit buffer.

flags One or more of the characters '+', '−', '#', 'p', or 'l' (ell). The flag characters can be <blank>-separated, and in any order or combination. The characters '#', 'p', and 'l' shall cause lines to be written in the format specified by the **print** command with the specified *flags*.

The lines to be written are as follows:

1. All edit buffer lines written during the execution of the *ex* **&**, **~**, **list**, **number**, **open**, **print**, **s**, **visual**, and **z** commands shall be written as specified by *flags*.
2. After the completion of an *ex* command with a flag as an argument, the current line shall be written as specified by *flags*, unless the current line was the last line written by the command.

The characters '+' and '−' cause the value of the current line after the execution of the *ex* command to be adjusted by the offset address as described in **Addressing in ex** (on page 2571). This adjustment shall occur before the current line is written as described in 2. above.

The default for *flags* shall be none.

buffer One of a number of named areas for holding text. The named buffers are specified by the alphanumeric characters of the POSIX locale. There shall also be one ''unnamed'' buffer. When no buffer is specified for editor commands that use a buffer, the unnamed buffer shall be used. Commands that store text into buffers shall store the text as it was before the command took effect, and shall store text occurring earlier in the file before text occurring later in the file, regardless of how the text region was specified. Commands that store text into buffers shall store the text into the unnamed buffer as well as any specified buffer.

In *ex* commands, buffer names are specified as the name by itself. In open or visual mode commands the name is preceded by a double quote ('"') character.

If the specified buffer name is an uppercase character, and the buffer contents are to be modified, the buffer shall be appended to rather than being overwritten. If the buffer is not being modified, specifying the buffer name in lowercase and uppercase shall have identical results.

There shall also be buffers named by the numbers 1 through 9. In open and visual mode, if a region of text including characters from more than a single line is being modified by the *vi* **c** or **d** commands, the motion character associated with the **c** or **d** commands specifies that the buffer text shall be in line mode, or the commands **%**, **‘**, **/**, **?**, **(**, **)**, **N**, **n**, **{**, or **}** are used to define a region of text for the **c** or **d** commands, the contents of buffers 1 through 8 shall be moved into the buffer named by the next numerically greater value, the contents of buffer 9 shall be discarded, and the region of text shall be copied into buffer 1. This shall be in addition to copying the text into a user-specified buffer or unnamed buffer, or both. Numeric buffers can be specified as a source buffer for open and visual mode commands; however, specifying a numeric buffer as the write target of an open or visual mode command shall have unspecified results.

The text of each buffer shall have the characteristic of being in either line or character mode. Appending text to a non-empty buffer shall set the mode to match the characteristic of the text being appended. Appending text to a buffer shall cause the creation of at least one additional line in the buffer. All text stored into

buffers by *ex* commands shall be in line mode. The *ex* commands that use buffers as the source of text specify individually how buffers of different modes are handled. Each open or visual mode command that uses buffers for any purpose specifies individually the mode of the text stored into the buffer and how buffers of different modes are handled.

file Command text used to derive a path name. The default shall be the current path name, as defined previously, in which case, if no current path name has yet been established it shall be an error, except where specifically noted in the individual command descriptions that follow. If the command text contains any of the characters '~', '{', '[', '*', '?', '$', '`', '`', '"', and '\', it shall be subjected to the process of ''shell expansions'', as described below; if more than a single path name results and the command expects only one, it shall be an error.

The process of shell expansions in the editor shall be done as follows. The *ex* utility shall pass two arguments to the program named by the shell edit option; the first shall be **–c**, and the second shall be the string `"echo"` and the command text as a single argument. The standard output and standard error of that command shall replace the command text.

! A character that can be appended to the command name to modify its operation, as detailed in the individual command descriptions. With the exception of the *ex* **read**, **write**, and **!** commands, the '!' character shall only act as a modifier if there are no <blank> characters between it and the command name.

remembered search direction
The *vi* commands **N** and **n** begin searching in a forwards or backwards direction in the edit buffer based on a remembered search direction, which is initially unset, and is set by the *ex* **global**, **v**, **s**, and **tag** commands, and the *vi* **/** and **?** commands.

Abbreviate

Synopsis: `ab[`*`breviate`*`][`*`lhs rhs`*`]`

If *lhs* and *rhs* are not specified, write the current list of abbreviations and do nothing more.

Implementations may restrict the set of characters accepted in *lhs* or *rh*, except that printable characters and <blank> characters shall not be restricted. Additional restrictions shall be implementation-defined.

In both *lhs* and *rhs*, any character may be escaped with a <control>-V, in which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

In open and visual text input mode, if a non-word or <ESC> character that is not escaped by a <control>-V character is entered after a word character, a check shall be made for a set of characters matching *lhs*, in the text input entered during this command. If it is found, the effect shall be as if *rhs* was entered instead of *lhs*.

The set of characters that are checked is defined as follows:

1. If there are no characters inserted before the word and non-word or <ESC> characters that triggered the check, the set of characters shall consist of the word character.
2. If the character inserted before the word and non-word or <ESC> characters that triggered the check is a word character, the set of characters shall consist of the characters inserted immediately before the triggering characters that are word characters, plus the triggering word character.

3. If the character inserted before the word and non-word or <ESC> characters that triggered the check is not a word character, the set of characters shall consist of the characters that were inserted before the triggering characters that are neither <blank> characters nor word characters, plus the triggering word character.

It is unspecified whether the *lhs* argument entered for the *ex* **abbreviate** and **unabbreviate** commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the effect of the command shall be as if the replacement had not occurred.

Current line: Unchanged.

Current column: Unchanged.

Append

Synopsis: **[***1addr***]** a**[**ppend**][**!**]**

Enter text input mode; the input text shall be placed after the specified line. If line zero is specified, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with '!' shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the specified line, or to the first line of the edit buffer if a line of zero was specified, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Arguments

Synopsis: ar**[***gs***]**

Write the current argument list, with the current argument-list entry, if any, between '[' and ']' characters.

Current line: Unchanged.

Current column: Unchanged.

Change

Synopsis: **[***2addr***]** c**[**hange**][**!**][***count***]**

Enter *ex* text input mode; the input text shall replace the specified lines. The specified lines shall be copied into the unnamed buffer, which shall become a line mode buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with '!' shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the first address, or to the first line of the edit buffer if there are no lines preceding the first address, or to zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Change Directory

Synopsis: `chd[ir][!][`*`directory`*`]`
`cd[!][`*`directory`*`]`

Change the current working directory to *directory*.

If no *directory* argument is specified, and the *HOME* environment variable is set to a non-null and non-empty value, *directory* shall default to the value named in the *HOME* environment variable. If the *HOME* environment variable is empty or is undefined, the default value of *directory* is implementation-defined.

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, and the current path name does not begin with a '//', it shall be an error.

Current line: Unchanged.

Current column: Unchanged.

Copy

Synopsis: `[`*`2addr`*`] co[py] `*`1addr`*` [`*`flags`*`]`
`[`*`2addr`*`] t `*`1addr`*` [`*`flags`*`]`

Copy the specified lines after the specified destination line; line zero specifies that the lines shall be placed at the beginning of the edit buffer.

Current line: Set to the last line copied.

Current column: Set to non-<blank>.

Delete

Synopsis: `[`*`2addr`*`] d[elete][`*`buffer`*`][`*`count`*`][`*`flags`*`]`

Delete the specified lines into a buffer (defaulting to the unnamed buffer), which shall become a line-mode buffer.

Flags can immediately follow the command name; see **Command Line Parsing in ex** (on page 2573).

Current line: Set to the line following the deleted lines, or to the last line in the edit buffer if that line is past the end of the edit buffer, or to zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Edit

Synopsis: `e[dit][!][+`*`command`*`][`*`file`*`]`
`ex[!][+`*`command`*`][`*`file`*`]`

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If *file* is specified, replace the current contents of the edit buffer with the current contents of *file*, and set the current path name to *file*. If *file* is not specified, replace the current contents of the edit buffer with the current contents of the file named by the current path name. If for any reason the current contents of the file cannot be accessed, the edit buffer shall be empty.

The **+***command* option shall be <blank> character-delimited; <blank> characters within **+***command* can be escaped by preceding them with a backslash character. The **+***command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been

14245 replaced and the current line and column have been set.

14246 If the edit buffer is empty:

14247 *Current line*: Set to 0.

14248 *Current column*: Set to 1.

14249 Otherwise, if executed while in *ex* command mode or if the **+***command* argument is specified:

14250 *Current line*: Set to the last line of the edit buffer.

14251 *Current column*: Set to non-<blank>.

14252 Otherwise, if *file* is omitted or results in the current path name:

14253 *Current line*: Set to the first line of the edit buffer.

14254 *Current column*: Set to non-<blank>.

14255 Otherwise, if *file* is the same as the last file edited, the line and column shall be set as follows; if
14256 the file was previously edited, the line and column may be set as follows:

14257 *Current line*: Set to the last value held when that file was last edited. If this value is not a valid
14258 line in the new edit buffer, set to the first line of the edit buffer.

14259 *Current column*: If the current line was set to the last value held when the file was last edited, set
14260 to the last value held when the file was last edited. Otherwise, or if the last value is not a valid
14261 column in the new edit buffer, set to non-<blank>.

14262 Otherwise:

14263 *Current line*: Set to the first line of the edit buffer.

14264 *Current column*: Set to non-<blank>.

14265 **File**

14266 *Synopsis*: **f[**ile**][***file***]**

14267 If a *file* argument is specified, the alternate path name shall be set to the current path name, and
14268 the current path name shall be set to *file*.

14269 Write an informational message. If the file has a current path name, it shall be included in this
14270 message; otherwise, the message shall indicate that there is no current path name. If the edit
14271 buffer contains lines, the current line number and the number of lines in the edit buffer shall be
14272 included in this message; otherwise, the message shall indicate that the edit buffer is empty. If
14273 the edit buffer has been modified since the last complete write, this fact shall be included in this
14274 message. If the **readonly** edit option is set, this fact shall be included in this message. The
14275 message may contain other unspecified information.

14276 *Current line*: Unchanged.

14277 *Current column*: Unchanged.

14278 **Global**

14279 *Synopsis*: **[***2addr***]** g**[**lobal**]** */pattern/* **[***commands***]**
14280 **[***2addr***]** v */pattern/* **[***commands***]**

14281 The optional '!' character after the **global** command shall be the same as executing the **v**
14282 command.

14283 If *pattern* is empty (for example, "//") or not specified, the last regular expression used in the
14284 editor command shall be used as the *pattern*. The *pattern* can be delimited by slashes (shown in |
14285 the Synopsis), as well as any non-alphanumeric or non-<blank> character other than backslash, |
14286 vertical line, double quote, or <newline>.

14287 If no lines are specified, the lines shall default to the entire file.

14288 The **global** and **v** commands are logically two-pass operations. First, mark the lines within the
14289 specified lines that match (**global**) or do not match (**v** or **global!**) the specified pattern. Second,
14290 execute the *ex* commands given by *commands*, with the current line ('.') set to each marked |
14291 line. If an error occurs during this process, or the contents of the edit buffer are replaced (for
14292 example, by the *ex* **:edit** command) an error message shall be written and no more commands
14293 resulting from the execution of this command shall be processed.

14294 Multiple *ex* commands can be specified by entering multiple commands on a single line using a
14295 vertical line to delimit them, or one per line, by escaping each <newline> with a backslash.

14296 If no commands are specified:

14297 1. If in *ex* command mode, it shall be as if the **print** command were specified.

14298 2. Otherwise, no command shall be executed.

14299 For the **append**, **change**, and **insert** commands, the input text shall be included as part of the
14300 command, and the terminating period can be omitted if the command ends the list of
14301 commands. The **open** and **visual** commands can be specified as one of the commands, in which
14302 case each marked line shall cause the editor to enter open or visual mode. If open or visual mode
14303 is exited using the *vi* **Q** command, the current line shall be set to the next marked line, and open
14304 or visual mode reentered, until the list of marked lines is exhausted.

14305 The **global**, **v**, and **undo** commands cannot be used in *commands*. Marked lines may be deleted |
14306 by commands executed for lines occurring earlier in the file than the marked lines. In this case, |
14307 no commands shall be executed for the deleted lines. |

14308 If the remembered search direction is not set, the **global** and **v** commands shall set it to forward.

14309 The **autoprint** and **autoindent** edit options shall be inhibited for the duration of the **g** or **v**
14310 command.

14311 *Current line*: If no commands executed, set to the last marked line. Otherwise, as specified for
14312 the executed *ex* commands.

14313 *Current column*: If no commands are executed, set to non-<blank>; otherwise, as specified for the
14314 individual *ex* commands.

Insert

Synopsis: **[***1addr***]** **i[**nsert**][**!**]**

Enter *ex* text input mode; the input text shall be placed before the specified line. If the line is zero or 1, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with '!' shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the specified line, or to the first line of the edit buffer if there are no lines preceding the specified line, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Join

Synopsis: **[***2addr***]** **j[**oin**][**!**][***count***][***flags***]**

If *count* is specified:

If no address was specified, the **join** command shall behave as if *2addr* were the current line and the current line plus *count* (., . + *count*).

If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the specified address plus *count* (*addr*,*addr* + *count*).

If two addresses were specified, the **join** command shall behave as if an additional address, equal to the last address plus *count* –1 (*addr1*,*addr2*,*addr2* + *count* –1), was specified.

If this would result in a second address greater than the last line of the edit buffer, it shall be corrected to be equal to the last line of the edit buffer.

If no *count* is specified:

If no address was specified, the **join** command shall behave as if *2addr* were the current line and the next line (., . +1).

If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the next line (*addr*,*addr* +1).

Join the text from the specified lines together into a single line, which shall replace the specified lines.

If a '!' character is appended to the command name, the **join** shall be without modification of any line, independent of the current locale.

Otherwise, in the POSIX locale, set the current line to the first of the specified lines, and then, for each subsequent line, proceed as follows:

1. Discard leading <space>s from the line to be joined.
2. If the line to be joined is now empty, delete it, and skip steps 3 through 5.
3. If the current line ends in a <blank> character, or the first character of the line to be joined is a ')' character, join the lines without further modification.
4. If the last character of the current line is a '.', join the lines with two <space> characters between them.

5. Otherwise, join the lines with a single <space> character between them.

Current line: Set to the first line specified.

Current column: Set to non-<blank>.

List

Synopsis: **[***2addr***]** l**[**ist**][***count***][***flags***]**

This command shall be equivalent to the *ex* command:

[*2addr***]** p**[**rint**][***count***]** l**[***flags***]**

See **Print** (on page 2590).

Map

Synopsis: map**[**!**][***lhs rhs***]**

If *lhs* and *rhs* are not specified:

1. If '!' is specified, write the current list of text input mode maps.
2. Otherwise, write the current list of command mode maps.
3. Do nothing more.

Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable characters and <blank> characters shall not be restricted. Additional restrictions shall be implementation-defined. In both *lhs* and *rhs*, any character can be escaped with a <control>-V, in which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

If the character '!' is appended to the **map** command name, the mapping shall be effective during open or visual text input mode rather than **open** or **visual** command mode. This allows *lhs* to have two different **map** definitions at the same time: one for command mode and one for text input mode.

For command mode mappings:

When the *lhs* is entered as any part of a *vi* command in open or visual mode (but not as part of the arguments to the command), the action shall be as if the corresponding *rhs* had been entered.

If any character in the command, other than the first, is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether implementations shall support **map** commands where the *lhs* is more than a single character in length, where the first character of the *lhs* is printable.

If *lhs* contains more than one character and the first character is '#', followed by a sequence of digits corresponding to a numbered function key, then when this function key is typed it shall be mapped to *rhs*. Characters other than digits following a '#' character also represent the function key named by the characters in the *lhs* following the '#' and may be mapped to *rhs*. It is unspecified how function keys are named or what function keys are supported.

For text input mode mappings:

When the *lhs* is entered as any part of text entered in open or visual text input modes, the action shall be as if the corresponding *rhs* had been entered.

If any character in the input text is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether the *lhs* argument entered for the **map** or **unmap** commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the effect of the command shall be as if the replacement had not occurred.

If only part of the *lhs* is entered, it is unspecified how long the editor will wait for additional, possibly matching characters before treating the already entered characters as not matching the *lhs*.

The *rhs* characters shall themselves be subject to remapping, unless otherwise specified by the **remap** edit option, except that if the characters in *lhs* occur as prefix characters in *rhs*, those characters shall not be remapped.

On block-mode terminals, the mapping need not occur immediately (for example, it may occur after the terminal transmits a group of characters to the system), but it shall achieve the same results as if it occurred immediately.

Current line: Unchanged.

Current column: Unchanged.

Mark

Synopsis: `[`*1addr*`]` ma`[`rk`]` *character*
`[`*1addr*`]` k *character*

Implementations shall support *character* values of a single lowercase letter of the POSIX locale and the characters `'''` and `'''`; support of other characters is implementation-defined.

If executing the *vi* **m** command, set the specified mark to the current line and 1-based numbered character referenced by the current column, if any; otherwise, column position 1.

Otherwise, set the specified mark to the specified line and 1-based numbered first non-<blank> character in the line, if any; otherwise, the last character in the line, if any; otherwise, column position 1.

The mark shall remain associated with the line until the mark is reset or the line is deleted. If a deleted line is restored by a subsequent **undo** command, any marks previously associated with the line, which have not been reset, shall be restored as well. Any use of a mark not associated with a current line in the edit buffer shall be an error.

The marks **‘** and **’** shall be set as described previously, immediately before the following events occur in the editor:

1. The use of `'$'` as an *ex* address
2. The use of a positive decimal number as an *ex* address
3. The use of a search command as an *ex* address
4. The use of a mark reference as an *ex* address
5. The use of the following open and visual mode commands: <control>-], **%**, **(**, **)**, **[**, **]**, **{**, **}**.
6. The use of the following open and visual mode commands: **’**, **G**, **H**, **L**, **M**, **z** if the current line will change as a result of the command

7. The use of the open and visual mode commands: **/**, **?**, **N**, **‘**, **n** if the current line or column will change as a result of the command
8. The use of the *ex* mode commands: **z**, **undo**, **global**, **v**

For rules 1., 2., 3., and 4., the ‘ and ’ marks shall not be set if the *ex* command is parsed as specified by rule 6.a. in **Command Line Parsing in ex** (on page 2573).

For rules 5., 6., and 7., the ‘ and ’ marks shall not be set if the commands are used as motion commands in open and visual mode.

For rules 1., 2., 3., 4., 5., 6., 7., and 8., the ‘ and ’ marks shall not be set if the command fails.

The ‘ and ’ marks shall be set as described previously, each time the contents of the edit buffer are replaced (including the editing of the initial buffer), if in open or visual mode, or if in **ex** mode and the edit buffer is not empty, before any commands or movements (including commands or movements specified by the **–c** or **–t** options or the **+***command* argument) are executed on the edit buffer. If in open or visual mode, the marks shall be set as if executing the *vi* **m** command; otherwise, as if executing the *ex* **mark** command.

When changing from **ex** mode to open or visual mode, if the ‘ and ’ marks are not already set, the ‘ and ’ marks shall be set as described previously.

Current line: Unchanged.

Current column: Unchanged.

Move

Synopsis: **[***2addr***]** m**[**ove**]** *1addr* **[***flags***]**

Move the specified lines after the specified destination line. A destination of line zero specifies that the lines shall be placed at the beginning of the edit buffer. It shall be an error if the destination line is within the range of lines to be moved.

Current line: Set to the last of the moved lines.

Current column: Set to non-<blank>.

Next

Synopsis: n**[**ext**][**!**][+***command***][***file ...**]**

If no ’!’ is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If one or more files is specified:

1. Set the argument list to the specified file names.
2. Set the current argument list reference to be the first entry in the argument list.
3. Set the current path name to the first file name specified.

Otherwise:

1. It shall be an error if there are no more file names in the argument list after the file name currently referenced.
2. Set the current path name and the current argument list reference to the file name after the file name currently referenced in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current path name. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

The **+***command* option shall be <blank> character-delimited; <blank> characters can be escaped by preceding them with a backslash character. The **+***command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Number

Synopsis: **[***2addr***]** nu**[**mber**][***count***][***flags***]**
[*2addr***]** #**[***count***][***flags***]**

These commands shall be equivalent to the *ex* command:

[*2addr***]** p**[**rint**][***count***]** #**[***flags***]**

See **Print** (on page 2590).

Open

Synopsis: **[***1addr***]** o**[**pen**]** */pattern/* **[***flags***]**

This command need not be supported on block-mode terminals or terminals with insufficient capabilities. If standard input, standard output, or standard error are not terminal devices, the results are unspecified.

Enter open mode.

The trailing delimiter can be omitted from pattern at the end of the command line. If pattern is empty (for example, "//") or not specified, the last regular expression used in the editor shall be used as the pattern. The pattern can be delimited by slashes (shown in the Synopsis), as well as any alphanumeric, or non-<blank> character other than backslash, vertical line, double quote, or <newline> character.

Current line: Set to the specified line.

Current column: Set to non-<blank>.

Preserve

Synopsis: pre**[**serve**]**

Save the edit buffer in a form that can later be recovered by using the **–r** option or by using the *ex* **recover** command. After the file has been preserved, a mail message shall be sent to the user. This message shall be readable by invoking the *mailx* utility. The message shall contain the name of the file, the time of preservation, and an *ex* command that could be used to recover the file. Additional information may be included in the mail message.

Current line: Unchanged.

Current column: Unchanged.

Print

Synopsis: **[***2addr***]** p**[**rint**][***count***][***flags***]**

Write the addressed lines. The behavior is unspecified if the number of columns on the display is less than the number of columns required to write any single character in the lines being written.

Non-printable characters, except for the <tab> character, shall be written as implementation-defined multi-character sequences.

If the **#** flag is specified or the **number** edit option is set, each line shall be preceded by its line number in the following format:

"%6dΔΔ", *<line number>*

If the **l** flag is specified or the **list** edit option is set:

1. The characters listed in the Base Definitions volume of IEEE Std. 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as the corresponding escape sequence.
2. Non-printable characters not in the Base Definitions volume of IEEE Std. 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than 9 bits, the format used for non-printable characters is implementation-defined.
3. The end of each line shall be marked with a '$', and literal '$' characters within the line shall be written with a preceding backslash.

Long lines shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output terminal, considering the number of columns of the terminal.

If a line is folded, and the **l** flag is not specified and the **list** edit option is not set, it is unspecified whether a multi-column character at the folding position is separated; it shall not be discarded.

Current line: Set to the last written line.

Current column: Unchanged if the current line is unchanged; otherwise, set to non-<blank>.

Put

Synopsis: **[***1addr***]** pu**[**t**][***buffer***]**

Append text from the specified buffer (by default, the unnamed buffer) to the specified line; line zero specifies that the text shall be placed at the beginning of the edit buffer. Each portion of a line in the buffer shall become a new line in the edit buffer, regardless of the mode of the buffer.

Current line: Set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Quit

Synopsis: q**[**uit**][**!**]**

If no '!' is appended to the command name:

1. If the edit buffer has been modified since the last complete write, it shall be an error.
2. If there are file names in the argument list after the file name currently referenced, and the last command was not a **quit**, **wq**, **xit**, or **ZZ** (see **Exit** (on page 3235)) command, it shall be an error.

Otherwise, terminate the editing session.

Read

Synopsis: **[***1addr***]** r**[**ead**][**!**][***file***]**

If '!' is not the first non-<blank> character to follow the command name, a copy of the specified file shall be appended into the edit buffer after the specified line; line zero specifies that the copy shall be placed at the beginning of the edit buffer. The number of lines and bytes read shall be written. If no *file* is named, the current path name shall be the default. If there is no current path name, then *file* shall become the current path name. If there is no current path name or *file* operand, it shall be an error. Specifying a *file* that is not of type regular shall have unspecified results.

Otherwise, if *file* is preceded by '!', the rest of the line after the '!' shall have '%', '#', and '!' characters expanded as described in **Command Line Parsing in ex** (on page 2573).

The *ex* utility shall then pass two arguments to the program named by the *shell* edit option; the first shall be **–c** and the second shall be the expanded arguments to the **read** command as a single argument. The standard input of the program shall be set to the standard input of the *ex* program when it was invoked. The standard error and standard output of the program shall be appended into the edit buffer after the specified line.

Each line in the copied file or program output (as delimited by <newline> characters or the end of the file or output if it is not immediately preceded by a <newline> character), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> character pairs in the output shall be treated as single <newline> characters.

The special meaning of the '!' following the **read** command can be overridden by escaping it with a backslash character.

Current line: If no lines are added to the edit buffer, unchanged. Otherwise, if in open or visual mode, set to the first line entered into the edit buffer. Otherwise, set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Recover

Synopsis: rec**[**over**][**!**]** ***file***

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If no *file* operand is specified, then the current path name shall be used. If there is no current path name or *file* operand, it shall be an error.

If no recovery information has previously been saved about *file*, the **recover** command shall behave identically to the **edit** command, and an informational message to this effect shall be written.

Otherwise, set the current path name to *file*, and replace the current contents of the edit buffer with the recovered contents of *file*. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. The editor shall behave as if the contents of the edit buffer have already been modified.

Current file: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Rewind

Synopsis: `rew[ind][!]`

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If the argument list is empty, it shall be an error.

The current argument list reference and the current path name shall be set to the first file name in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current path name. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Set

Synopsis: `se[t][`*option*`[=[`*value*`]] ...][no`*option* `...][`*option*`? ...][all]`

When no arguments are specified, write the value of the **term** edit option and those options whose values have been changed from the default settings; when the argument *all* is specified, write all of the option values.

Giving an option name followed by the character `'?'` shall cause the current value of that option to be written. The `'?'` can be separated from the option name by zero or more <blank> characters. The `'?'` shall be necessary only for Boolean valued options. Boolean options can be given values by the form **set** *option* to turn them on or **set no***option* to turn them off; string and numeric options can be assigned by the form **set** *option*=*value*. Any <blank> characters in strings can be included as is by preceding each <blank> with an escaping backslash. More than one option can be set or listed by a single set command by specifying multiple arguments, each separated from the next by one or more <blank> characters.

See **Edit Options in ex** (on page 2602) for details about specific options.

Current line: Unchanged.

Current column: Unchanged.

Shell

Synopsis: `sh[ell]`

Invoke the program named in the **shell** edit option with the single argument **–i** (interactive mode). Editing shall be resumed when the program exits.

Current line: Unchanged.

Current column: Unchanged.

14627 **Source**

14628 *Synopsis*: `so[urce] file`

14629 Read and execute *ex* commands from *file*. Lines in the file that contain no characters or only
14630 <blank> characters shall be ignored.

14631 *Current line*: As specified for the individual *ex* commands.

14632 *Current column*: As specified for the individual *ex* commands.

14633 **Substitute**

14634 *Synopsis*: `[2addr] s[ubstitute][/pattern/repl/[options][count][flags]]`
14635 `[2addr] &[options][count][flags]]`
14636 `[2addr] ~[options][count][flags]]`

14637 Replace the first instance of the pattern *pattern* by the string *repl* on each specified line. (See
14638 **Regular Expressions in ex** (on page 2601) and **Replacement Strings in ex** (on page 2602).) Any
14639 non-alphabetic, non-<blank> delimiter other than `'\\'`, `'|'`, double quote, or <newline> |
14640 character can be used instead of `'/'`. Backslash characters can be used to escape delimiters,
14641 backslash characters, and other special characters.

14642 The trailing delimiter can be omitted from *pattern* or from *repl* at the end of the command line. If
14643 both *pattern* and *repl* are not specified or are empty (for example, `"//"`), the last **s** command
14644 shall be repeated. If only *pattern* is not specified or is empty, the last regular expression used in
14645 the editor shall be used as the pattern. If only *repl* is not specified or is empty, the pattern shall be
14646 replaced by nothing. If the entire replacement pattern is `'%'`, the last replacement pattern to an
14647 **s** command shall be used.

14648 Entering a <carriage-return> in *repl* (which requires an escaping backslash in *ex* mode and an
14649 escaping <control>-V in open or *vi* mode) shall split the line at that point, creating a new line in
14650 the edit buffer. The <carriage-return> shall be discarded.

14651 If options include the letter `'g'` (**global**), all non-overlapping instances of the pattern in the line
14652 shall be replaced.

14653 If options includes the letter `'c'` (**confirm**), then before each substitution the line shall be
14654 written; the written line shall reflect all previous substitutions. On the following line, <space>
14655 characters shall be written beneath the characters from the line that are before the *pattern* to be
14656 replaced, and `'^'` characters written beneath the characters included in the *pattern* to be
14657 replaced. The *ex* utility shall then wait for a response from the user. An affirmative response
14658 shall cause the substitution to be done, while any other input shall not make the substitution. An
14659 affirmative response shall consist of a line with the affirmative response (as defined by the
14660 current locale) at the beginning of the line. This line shall be subject to editing in the same way as
14661 the *ex* command line.

14662 If interrupted (see the ASYNCHRONOUS EVENTS section), any modifications confirmed by the
14663 user shall be preserved in the edit buffer after the interrupt.

14664 If the remembered search direction is not set, the **s** command shall set it to forward.

14665 In the second Synopsis, the **&** command shall repeat the previous substitution, as if the **&**
14666 command were replaced by:

14667 `s/pattern/repl/`

14668 where *pattern* and *repl* are as specified in the previous **s**, **&**, or **~** command.

14669 In the third Synopsis, the **~** command shall repeat the previous substitution, as if the '~' were
14670 replaced by:

14671 s/*pattern*/*repl*/

14672 where *pattern* shall be the last regular expression specified to the editor, and *repl* shall be from
14673 the previous substitution (including **&** and **~**) command.

14674 These commands shall be affected by the *LC_MESSAGES* environment variable.

14675 *Current line*: Set to the last line in which a substitution occurred, or, unchanged if no
14676 substitution occurred.

14677 *Current column*: Set to non-<blank>.

14678 **Suspend**

14679 *Synopsis*: su[spend][!]
14680 st[op][!]

14681 Allow control to return to the invoking process; *ex* shall suspend itself as if it had received the
14682 SIGTSTP signal. The suspension shall occur only if job control is enabled in the invoking shell
14683 (see the description of *set* –**m**).

14684 These commands shall be affected by the **autowrite** and **writeany** edit options.

14685 The current **susp** character (see *stty*) shall have the same affect as the **suspend** command.

14686 **Tag**

14687 *Synopsis*: ta[g][!] *tagstring*

14688 The results are unspecified if the format of a tags file is not as specified by the *ctags* utility (see
14689 *ctags*) description.

14690 The **tag** command shall search for *tagstring* in the tag files referred to by the **tag** edit option, in
14691 the order they are specified, until a reference to *tagstring* is found. Files shall be searched from
14692 beginning to end. If no reference is found, it shall be an error and an error message to this effect
14693 shall be written. If the reference is not found, or if an error occurs while processing a file referred
14694 to in the **tag** edit option, it shall be an error, and an error message shall be written at the first
14695 occurrence of such an error.

14696 Otherwise, if the tags file contained a pattern, the pattern shall be treated as a regular expression
14697 used in the editor; for example, for the purposes of the **s** command.

14698 If the *tagstring* is in a file with a different name than the current path name, set the current path
14699 name to the name of that file, and replace the contents of the edit buffer with the contents of that
14700 file. In this case, if no '!' is appended to the command name, and the edit buffer has been
14701 modified since the last complete write, it shall be an error, unless the file is successfully written
14702 as specified by the **autowrite** option.

14703 This command shall be affected by the **autowrite**, **tag**, **taglength**, and **writeany** edit options.

14704 *Current line*: If the tags file contained a line number, set to that line number. If the line number is
14705 larger than the last line in the edit buffer, an error message shall be written and the current line
14706 shall be set as specified for the **edit** command.

14707 If the tags file contained a pattern, set to the first occurrence of the pattern in the file. If no
14708 matching pattern is found, an error message shall be written and the current line shall be set as
14709 specified for the **edit** command.

Current column: If the tags file contained a line-number reference and that line-number was not larger than the last line in the edit buffer, or if the tags file contained a pattern and that pattern was found, set to non-<blank>. Otherwise, set as specified for the **edit** command.

Unabbreviate

Synopsis: `una[bbrev]` *lhs*

If *lhs* is not an entry in the current list of abbreviations (see **Abbreviate** (on page 2580)), it shall be an error. Otherwise, delete *lhs* from the list of abbreviations.

Current line: Unchanged.

Current column: Unchanged.

Undo

Synopsis: `u[ndo]`

Reverse the changes made by the last command that modified the contents of the edit buffer, including **undo**. For this purpose, the **global**, **v**, **open**, and **visual** commands, and commands resulting from buffer executions and mapped character expansions, are considered single commands.

If no action that can be undone preceded the **undo** command, it shall be an error.

If the **undo** command restores lines that were marked, the mark shall also be restored unless it was reset subsequent to the deletion of the lines.

Current line:

1. If lines are added or changed in the file, set to the first line added or changed.
2. Set to the line before the first line deleted, if it exists.
3. Set to 1 if the edit buffer is not empty.
4. Set to zero.

Current column: Set to non-<blank>.

Unmap

Synopsis: `unm[ap][!]` *lhs*

If '`!`' is appended to the command name, and if *lhs* is not an entry in the list of text input mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of text input mode map definitions.

If no '`!`' is appended to the command name, and if *lhs* is not an entry in the list of command mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of command mode map definitions.

Current line: Unchanged.

Current column: Unchanged.

14744 **Version**

14745 *Synopsis*: `ve[rsion]`

14746 Write a message containing version information for the editor. The format of the message is
14747 unspecified.

14748 *Current line*: Unchanged.

14749 *Current column*: Unchanged.

14750 **Visual**

14751 *Synopsis*: `[`*`1addr`*`] vi[sual][`*`type`*`][`*`count`*`][`*`flags`*`]`

14752 If *ex* is currently in open or visual mode, the Synopsis and behavior of the visual command shall
14753 be the same as the **edit** command, as specified by **Edit** (on page 2582).

14754 Otherwise, this command need not be supported on block-mode terminals or terminals with
14755 insufficient capabilities. If standard input, standard output, or standard error are not terminal
14756 devices, the results are unspecified.

14757 If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in
14758 **window** (on page 2609)). If the `'^'` type character was also specified, the **window** edit option
14759 shall be set before being used by the type character.

14760 Enter visual mode. If *type* is not specified, it shall be as if a *type* of `'+'` was specified. The *type*
14761 shall cause the following effects:

14762 `+` Place the beginning of the specified line at the top of the display.

14763 `-` Place the end of the specified line at the bottom of the display.

14764 `.` Place the beginning of the specified line in the middle of the display.

14765 `^` If the specified line is less than or equal to the value of the **window** edit option, set the line
14766 to 1; otherwise, decrement the line by the value of the **window** edit option minus 1. Place
14767 the beginning of this line as close to the bottom of the displayed lines as possible, while still
14768 displaying the value of the **window** edit option number of lines.

14769 *Current line*: Set to the specified line.

14770 *Current column*: Set to non-<blank>.

14771 **Write**

14772 *Synopsis*: `[`*`2addr`*`] w[rite][!][>>][`*`file`*`]`
14773 `[`*`2addr`*`] w[rite][!][`*`file`*`]`
14774 `[`*`2addr`*`] wq[!][>>][`*`file`*`]`

14775 If no lines are specified, the lines shall default to the entire file.

14776 The command **wq** shall be equivalent to a **write** command followed by a **quit** command; **wq!**
14777 shall be equivalent to **write!** followed by **quit**. In both cases, if the **write** command fails, the
14778 **quit** shall not be attempted.

14779 If the command name is not followed by one or more <blank> characters, or *file* is not preceded
14780 by a `'!'` character, the **write** shall be to a file.

14781 1. If the `>>` argument is specified, and the file already exists, the lines shall be appended to
14782 the file instead of replacing its contents. If the `>>` argument is specified, and the file does
14783 not already exist, it is unspecified whether the write shall proceed as if the `>>` argument

had not been specified or if the write shall fail.

2. If the **readonly** edit option is set (see **readonly** (on page 2606)), the **write** shall fail.
3. If *file* is specified, and is not the current path name, and the file exists, the **write** shall fail.
4. If *file* is not specified, the current path name shall be used. If there is no current path name, the **write** command shall fail.
5. If the current path name is used, and the current path name has been changed by the **file** or **read** commands, and the file exists, the **write** shall fail. If the **write** is successful, subsequent **write**s shall not fail for this reason (unless the current path name is changed again).
6. If the whole edit buffer is not being written, and the file to be written exists, the **write** shall fail.

For rules 1., 2., 4., and 5., the **write** can be forced by appending the character '!' to the command name.

For rules 2., 4., and 5., the **write** can be forced by setting the **writeany** edit option.

Additional, implementation-defined tests may cause the **write** to fail.

If the edit buffer is empty, a file without any contents shall be written.

An informational message shall be written noting the number of lines and bytes written.

Otherwise, if the command is followed by one or more <blank> characters, and file is preceded by '!', the rest of the line after the '!' shall have '%', '#', and '!' characters expanded as described in **Command Line Parsing in ex** (on page 2573).

The *ex* utility shall then pass two arguments to the program named by the **shell** edit option; the first shall be **–c** and the second shall be the expanded arguments to the **write** command as a single argument. The specified lines shall be written to the standard input of the command. The standard error and standard output of the program. if any, shall be written as described for the **print** command. If the last character in that output is not a <newline> character, a <newline> shall be written at the end of the output.

The special meaning of the '!' following the **write** command can be overridden by escaping it with a backslash character.

Current line: Unchanged.

Current column: Unchanged.

Write and Exit

Synopsis: **[***2addr***]** x**[**it**][**!**][***file***]**

If the edit buffer has not been modified since the last complete **write**, **xit** shall be equivalent to the **quit** command, or if a '!' is appended to the command name, to **quit!**.

Otherwise, **xit** shall be equivalent to the **wq** command, or if a '!' is appended to the command name, to **wq!**.

Current line: Unchanged.

Current line: Unchanged.

Yank

Synopsis: **[***2addr***]** ya**[**nk**][***buffer***][***count***]**

Copy the specified lines to the specified buffer (by default, the unnamed buffer), which shall become a line-mode buffer.

Current line: Unchanged.

Current line: Unchanged.

Adjust Window

Synopsis: **[***1addr***]** z**[**!**][***type ...***][***count***][***flags***]**

If no line is specified, the current line shall be the default; if *type* is omitted as well, the current line value shall first be incremented by 1. If incrementing the current line would cause it to be greater than the last line in the edit buffer, it shall be an error.

If there are <blank> characters between the *type* argument and the preceding **z** command name or optional '!' character, it shall be an error.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in **window** (on page 2609)). If *count* is omitted, it shall default to 2 times the value of the **scroll** edit option, or if **!** was specified, the number of lines in the display minus 1.

If *type* is omitted, then *count* lines starting with the specified line shall be written. Otherwise, *count* lines starting with the line specified by the *type* argument shall be written.

The *type* argument shall change the lines to be written. The possible values of *type* are as follows:

– The specified line shall be decremented by the following value:

  (((number of ''–'' characters) x *count*) –1)

  If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

+ The specified line shall be incremented by the following value:

  (((number of ''+'' characters) –1) x *count*) +1

  If the calculation would result in a number greater than the last line in the edit buffer, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

=,. If more than a single '.' or '=' is specified, it shall be an error. The following steps shall be taken:

1. If *count* is zero, nothing shall be written.
2. Write as many of the *N* lines before the current line in the edit buffer as exist. If *count* or '!' was specified, *N* shall be:

   (*count* –1) /2

   Otherwise, *N* shall be:

   (*count* –3) /2

   If *N* is a number less than 3, no lines shall be written.

3. If '=' was specified as the type character, write a line consisting of the smaller of the number of columns in the display divided by two, or 40 '–' characters.
4. Write the current line.
5. Repeat step 3.
6. Write as many of the *N* lines after the current line in the edit buffer as exist. *N* shall be defined as in step 2. If *N* is a number less than 3, no lines shall be written. current line in the edit buffer as exist. If count is less than 3, no lines shall be written.

^ The specified line shall be decremented by the following value:

(((number of ''^'' characters) +1) x *count*) –1

If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

Current line: Set to the last line written, unless the type is **=**, in which case, set to the specified line.

Current column: Set to non-<blank>.

Escape

Synopsis: ! *command*
[*addr***]** ! *command*

The contents of the line after the '!' shall have '%', '#', and '!' characters expanded as described in **Command Line Parsing in ex** (on page 2573). If the expansion causes the text of the line to change, it shall be redisplayed, preceded by a single '!' character.

The *ex* utility shall execute the program named by the **shell** edit option. It shall pass two arguments to the program; the first shall be **–c**, and the second shall be the expanded arguments to the **!** command as a single argument.

If no lines are specified, the standard input, standard output, and standard error of the program shall be set to the standard input, standard output, and standard error of the *ex* program when it was invoked. In addition, a warning message shall be written if the edit buffer has been modified since the last complete write, and the **warn** edit option is set.

If lines are specified, they shall be passed to the program as standard input, and the standard output and standard error of the program shall replace those lines in the edit buffer. Each line in the program output (as delimited by <newline> characters or the end of the output if it is not immediately preceded by a <newline> character), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> character pairs in the output shall be treated as single <newline> characters. The specified lines shall be copied into the unnamed buffer before they are replaced, and the unnamed buffer shall become a line-mode buffer.

If in *ex* mode, a single '!' character shall be written when the program completes.

This command shall be affected by the **shell** and **warn** edit options. If no lines are specified, this command shall be affected by the **autowrite** and **writeany** edit options. If lines are specified, this command shall be affected by the **autoprint** edit option.

Current line:

1. If no lines are specified, unchanged.

2. Otherwise, set to the last line read in, if any lines are read in.
3. Otherwise, set to the line before the first line of the lines specified, if that line exists.
4. Otherwise, set to the first line of the edit buffer if the edit buffer is not empty.
5. Otherwise, set to zero.

Current column: If no lines are specified, unchanged. Otherwise, set to non-<blank>.

Shift Left

Synopsis: **[***2addr***] <[<** ...**][***count***][***flags***]**

Shift the specified lines to the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. Only leading <blank> characters shall be deleted or changed into other <blank> characters in shifting; other characters shall not be affected.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

Shift Right

Synopsis: **[***2addr***] >[>** ...**][***count***][***flags***]**

Shift the specified lines away from the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. The shift shall be accomplished by adding <blank> characters as a prefix to the line or changing leading <blank> characters into other <blank> characters. Empty lines shall not be changed.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

<control>-D

Synopsis: <control>-D

Write the next *n* lines, where *n* is the minimum of the values of the **scroll** edit option and the number of lines after the current line in the edit buffer. If the current line is the last line of the edit buffer it shall be an error.

Current line: Set to the last line written.

Current column: Set to non-<blank>.

Write Line Number

Synopsis: **[***1addr***] = [***flags***]**

If *line* is not specified, it shall default to the last line in the edit buffer. Write the line number of the specified line.

Current line: Unchanged.

Current column: Unchanged.

Execute

Synopsis: **[***2addr***] @** *buffer*
[*2addr***] *** *buffer*

If no buffer is specified or is specified as '@' or '*', the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

For each line specified by the addresses, set the current line ('.') to the specified line, and execute the contents of the named *buffer* (as they were at the time the **@** command was executed) as *ex* commands. For each line of a line-mode buffer, and all but the last line of a character-mode buffer, the *ex* command parser shall behave as if the line was terminated by a <newline> character.

If an error occurs during this process, or a line specified by the addresses does not exist when the current line would be set to it, or more than a single line was specified by the addresses, and the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written, and no more commands resulting from the execution of this command shall be processed.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Regular Expressions in ex

The *ex* utility shall support regular expressions that are a superset of the basic regular expressions described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions. A null regular expression ("//") shall be equivalent to the last regular expression encountered.

Regular expressions can be used in addresses to specify lines and, in some commands (for example, the **substitute** command), to specify portions of a line to be substituted.

The following constructs can be used to enhance the basic regular expressions:

\< Match the beginning of a *word*. (See the definition of *word* at the beginning of **Command Descriptions in ex** (on page 2578).)

\> Match the end of a *word*.

~ Match the replacement part of the last **substitute** command. The tilde ('~') character can be escaped in a regular expression to become a normal character with no special meaning. The backslash shall be discarded.

When the editor option **magic** is not set, the only characters with special meanings shall be '^' at the beginning of a pattern, '$' at the end of a pattern, and '\'. The characters '.', '*', '[', and '~' shall be treated as ordinary characters unless preceded by a '\'; when preceded by a '\' they shall regain their special meaning, or in the case of backslash, be handled as a single backslash. Backslashes used to escape other characters shall be discarded.

Replacement Strings in ex

The character '&' ('\&' if the editor option **magic** is not set) in the replacement string shall stand for the text matched by the pattern to be replaced. The character '~' ('\~' if **magic** is not set) shall be replaced by the replacement part of the previous **substitute** command. The sequence '\n', where *n* is an integer, shall be replaced by the text matched by the pattern enclosed in the *n*th set of parentheses '\(' and '\)'.

The strings '\l', '\u', '\L', and '\U' can be used to modify the case of elements in the replacement string (using the '\&' or "\"digit) notation. The string '\l' ('\u') shall cause the character that follows to be converted to lowercase (uppercase). The string '\L' ('\U') shall cause all characters subsequent to it to be converted to lowercase (uppercase) as they are inserted by the substitution until the string '\e' or '\E', or the end of the replacement string, is encountered.

Otherwise, any character following a backslash shall be treated as that literal character, and the escaping backslash shall be discarded.

An example of case conversion with the **s** command is as follows:

```
:p
The cat sat on the mat.
:s/\<.at\>/\u&/gp
The Cat Sat on the Mat.
:s/S\(.*\)M/S\U\1\eM/p
The Cat SAT ON THE Mat.
```

Edit Options in ex

The *ex* utility has a number of options that modify its behavior. These options have default settings, which can be changed using the **set** command.

Options are Boolean unless otherwise specified.

autoindent, ai

[Default *unset*]

If **autoindent** is set, each line in input mode shall be indented (using first as many <tab> characters as possible, as determined by the editor option **tabstop**, and then using <space> characters) to align with another line, as follows:

1. If in open or visual mode and the text input is part of a line-oriented command (see the EXTENDED DESCRIPTION in *vi*), align to the first column. Otherwise, if in open or visual mode, indentation for each line shall be set as follows:

   a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the <control>-D character in **Input Mode Commands in vi** (on page 3235).

   b. Otherwise, it shall be set to the indentation of the previous current line, if any; otherwise, to the first column.

2. For the *ex* **a**, **i**, and **c** commands, indentation for each line shall be set as follows:

   a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the *eof* character in **Scroll** (on page 2577).

15019 b. Otherwise, if the command is the *ex* **a** command, it shall be set to the line appended
15020 after, if any; otherwise to the first column.

15021 c. Otherwise, if the command is the *ex* **i** command, it shall be set to the line inserted
15022 before, if any; otherwise to the first column.

15023 d. Otherwise, if the command is the *ex* **c** command, it shall be set to the indentation of
15024 the line replaced.

15025 **autoprint, ap**

15026 [Default *set*]

15027 If **autoprint** is set, the current line shall be written after each *ex* command that modifies the
15028 contents of the current edit buffer, and after each **tag** command for which the tag search pattern
15029 was found or tag line number was valid, unless:

15030 1. The command was executed while in open or visual mode.

15031 2. The command was executed as part of a **global** or **v** command or **@** buffer execution.

15032 3. The command was the form of the **read** command that reads a file into the edit buffer.

15033 4. The command was the **append**, **change**, or **insert** command.

15034 5. The command was not terminated by a <newline> character.

15035 6. The current line shall be written by a flag specified to the command; for example, **delete #**
15036 shall write the current line as specified for the flag modifier to the **delete** command, and
15037 not as specified by the **autoprint** edit option.

15038 **autowrite, aw**

15039 [Default *unset*]

15040 If **autowrite** is set, and the edit buffer has been modified since it was last completely written to
15041 any file, the contents of the edit buffer shall be written as if the *ex* **write** command had been
15042 specified without arguments, before each command affected by the **autowrite** edit option is
15043 executed. Appending the character '!' to the command name of any of the *ex* commands
15044 except '!' shall prevent the write. If the write fails, it shall be an error and the command shall
15045 not be executed.

15046 **beautify, bf**

15047 XSI [Default *unset*]

15048 If **beautify** is set, all non-printable characters, other than <tab>, <newline>, and <form-feed>
15049 characters, shall be discarded from text read in from files.

15050 **directory, dir**

15051 [Default *implementation-defined*]

15052 The value of this option specifies the directory in which the editor buffer is to be placed. If this
15053 directory is not writable by the user, the editor shall quit.

edcompatible, ed

[Default *unset*]

Causes the presence of **g** and **c** suffixes on substitute commands to be remembered, and toggled by repeating the suffixes.

errorbells, eb

[Default *unset*]

If the editor is in *ex* mode, and the terminal does not support a standout mode (such as inverse video), and **errorbells** is set, error messages shall be preceded by alerting the terminal.

exrc

[Default *unset*]

If **exrc** is set, *ex* shall access any **.exrc** file in the current directory, as described in **Initialization in ex and vi** (on page 2569). If **exrc** is not set, *ex* shall ignore any **.exrc** file in the current directory during initialization, unless the current directory is that named by the *HOME* environment variable.

ignorecase, ic

[Default *unset*]

If **ignorecase** is set, characters that have uppercase and lowercase representations shall have those representations considered as equivalent for purposes of regular expression comparison.

The **ignorecase** edit option shall affect all remembered regular expressions; for example, unsetting the **ignorecase** edit option shall cause a subsequent *vi* **n** command to search for the last basic regular expression in a case-sensitive fashion.

lisp

[Default *unset*]

autoindent mode and the **(**, **)**, **{**, **}**, **[[**, and **]]** commands in visual mode are suitably modified for LISP code.

list

[Default *unset*]

If **list** is set, edit buffer lines written while in *ex* command mode shall be written as specified for the **print** command with the **l** flag specified. In open or visual mode, each edit buffer line shall be displayed as specified for the *ex* print command with the **l** flag specified. In open or visual text input mode, when the cursor does not rest on any character in the line, it shall rest on the `'$'` marking the end of the line.

magic

[Default *set*]

If **magic** is set, modify the interpretation of characters in regular expressions and substitution replacement strings (see **Regular Expressions in ex** (on page 2601) and **Replacement Strings in ex** (on page 2602)).

mesg

[Default *set*]

If **mesg** is set, the permission for others to use the **write** or **talk** commands to write to the terminal shall be turned on while in open or visual mode. The shell-level command *mesg* **n** shall take precedence over any setting of the *ex* **mesg** option; that is, if **mesg y** was issued before the editor started (or in a shell escape), such as:

```
:!mesg y
```

the **mesg** option in *ex* shall suppress incoming messages, but the **mesg** option shall not enable incoming messages if **mesg n** was issued.

number, nu

[Default *unset*]

If **number** is set, edit buffer lines written while in *ex* command mode shall be written with line numbers, in the format specified by the **print** command with the **#** flag specified. In *ex* text input mode, each line shall be preceded by the line number it will have in the file.

In open or visual mode, each edit buffer line shall be displayed with a preceding line number, in the format specified by the *ex* **print** command with the **#** flag specified. This line number shall not be considered part of the line for the purposes of evaluating the current column; that is, column position 1 shall be the first column position after the format specified by the **print** command.

paragraphs, para

[Default in the POSIX locale `IPLPPPQPP LIpplpipbp`]

The **paragraphs** edit option shall define additional paragraph boundaries for the open and visual mode commands. The **paragraphs** edit option can be set to a character string consisting of zero or more character pairs. It shall be an error to set it to an odd number of characters.

prompt

[Default *set*]

If **prompt** is set, *ex* command mode input shall be prompted for with a colon (`':'`); when unset, no prompt shall be written.

readonly

[Default *see text*]

If **readonly** edit option is set, read-only mode shall be enabled (see **Write** (on page 2596)). The **readonly** edit option shall be initialized to set if either of the following conditions are true:

- The command-line option –R was specified.
- Performing actions equivalent to the *access*( ) function called with the following arguments indicates that the file lacks write permission:
  1. The current path name is used as the *path* argument.
  2. The constant **W_OK** is used as the *amode* argument.

The **readonly** edit option may be initialized to set for other, implementation-defined reasons. The **readonly** edit option shall not be initialized to unset based on any special privileges of the user or process. The **readonly** edit option shall be reinitialized each time that the contents of the edit buffer are replaced (for example, by an **edit** or **next** command) unless the user has explicitly set it, in which case it shall remain set until the user explicitly unsets it. Once unset, it shall again be reinitialized each time that the contents of the edit buffer are replaced.

redraw

[Default *unset*]

The editor simulates an intelligent terminal on a dumb terminal. (Since this is likely to require a large amount of output to the terminal, it is useful only at high transmission speeds.)

remap

[Default *set*]

If **remap** is set, map translation shall allow for maps defined in terms of other maps; translation shall continue until a final product is obtained. If unset, only a one-step translation shall be done.

report

[Default 5]

The value of this **report** edit option specifies what number of lines being added, copied, deleted, or modified in the edit buffer will cause an informational message to be written to the user. The following conditions shall cause an informational message. The message shall contain the number of lines added, copied, deleted, or modified, but is otherwise unspecified.

- An *ex* or *vi* editor command, other than **open**, **undo**, or **visual**, that modifies at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **yank** or *vi* **y** or **Y** command, that copies at least the value of the **report** edit option plus 1 number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **global**, **v**, **open**, **undo**, or **visual** command or *ex* or *vi* buffer execution, that adds or deletes a total of at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written. (For example, if 3 lines were added and 8 lines deleted during an *ex* **visual** command, 5 would be the number compared against the **report** edit option after the command completed.

scroll, scr

[Default (number of lines in the display –1) / 2]

The value of the **scroll** edit option shall determine the number of lines scrolled by by the *ex* <control>-D and **z** commands. For the *vi* <control>-D and <control>-U commands, it shall be the initial number of lines to scroll when no previous <control>-D or <control>-U command has been executed.

sections

[Default in the POSIX locale `NHSHH HUnhsh`]

The **sections** edit option shall define additional section boundaries for the open and visual mode commands. The **sections** edit option can be set to a character string consisting of zero or more character pairs; it shall be an error to set it to an odd number of characters.

shell, sh

[Default from the environment variable *SHELL*]

The value of this option shall be a string. The default shall be taken from the *SHELL* environment variable. If the *SHELL* environment variable is null or empty, the *sh* (see *sh*) utility shall be the default.

shiftwidth, sw

[Default 8]

The value of this option shall give the width in columns of an indentation level used during autoindentation and by the shift commands (< and >).

showmatch, sm

[Default *unset*]

The functionality described for the **showmatch** edit option need not be supported on block-mode terminals or terminals with insufficient capabilities.

If **showmatch** is set, in open or visual mode, when a `')'` or `'}'` is typed, if the matching `'('` or `'{'` is currently visible on the display, the matching `'('` or `'{'` shall be flagged moving the cursor to its location for an unspecified amount of time.

showmode

[Default *unset*]

If **showmode** is set, in open or visual mode, the current mode that the editor is in shall be displayed on the last line of the display. Command mode and text input mode shall be differentiated; other unspecified modes and implementation-defined information may be displayed.

15193 **slowopen**

15194 [Default *unset*]

15195 If **slowopen** is set during open and visual text input modes, the editor shall not update portions
15196 of the display other than those screen columns that display the characters entered by the user
15197 (see **Input Mode Commands in vi** (on page 3235)).

15198 **tabstop, ts**

15199 [Default 8]

15200 The value of this edit option shall specify the column boundary used by a <tab> character in the
15201 display (see **autoprint, ap** (on page 2603) and **Input Mode Commands in vi** (on page 3235)).

15202 **taglength, tl**

15203 [Default zero]

15204 The value of this edit option shall specify the maximum number of characters that are
15205 considered significant in the user-specified tag name and in the tag name from the tags file. If the
15206 value is zero, all characters in both tag names shall be significant.

15207 **tags**

15208 [Default *see text*]

15209 The value of this edit option shall be a string of <blank> character-delimited path names of files
15210 used by the **tag** command. The default value is unspecified.

15211 **term**

15212 [Default from the environment variable *TERM*]

15213 The value of this edit option shall be a string. The default shall be taken from the *TERM* variable
15214 in the environment. If the *TERM* environment variable is empty or null, the default is
15215 unspecified. The editor shall use the value of this edit option to determine the type of the display
15216 device.

15217 The results are unspecified if the user changes the value of the term edit option after editor
15218 initialization.

15219 **terse**

15220 [Default *unset*]

15221 If **terse** is set, error messages may be less verbose. However, except for this caveat, error
15222 messages are unspecified. Furthermore, not all error messages need change for different settings
15223 of this option.

15224 **warn**

15225 [Default *set*]

15226 If **warn** is set, and the contents of the edit buffer have been modified since they were last
15227 completely written, the editor shall write a warning message before certain **!** commands (see
15228 **Escape** (on page 2599)).

window

[Default *see text*]

A value used in open and visual mode, by the <control>-B and <control>-F commands, and, in visual mode, to specify the number of lines displayed when the screen is repainted.

If the **−w** command-line option is not specified, the default value shall be set to the value of the *LINES* environment variable. If the *LINES* environment variable is empty or null, the default shall be the number of lines in the display minus 1.

Setting the **window** edit option to zero or to a value greater than the number of lines in the display minus 1 (either explicitly or based on the **−w** option or the *LINES* environment variable) shall cause the **window** edit option to be set to the number of lines in the display minus 1.

The baud rate of the terminal line may change the default in an implementation-defined manner.

wrapmargin, wm

[Default 0]

If the value of this edit option is zero, it shall have no effect.

If not in the POSIX locale, the effect of this edit option is implementation-defined.

Otherwise, it shall specify a number of columns from the ending margin of the terminal.

During open and visual text input modes, for each character for which any part of the character is displayed in a column that is less than **wrapmargin** columns from the ending margin of the screen, the editor shall behave as follows:

1. If the character triggering this event is a <blank> character, it, and all immediately preceding <blank> characters on the current line entered during the execution of the current text input command, shall be discarded, and the editor shall behave as if the user had entered a single <newline> character instead. In addition, if the next user-entered character is a <space> character, it shall be discarded as well.
2. Otherwise, if there are one or more <blank> characters on the current line immediately preceding the last group of inserted non-<blank> characters which was entered during the execution of the current text input command, the <blank> characters shall be replaced as if the user had entered a single <newline> character instead.

If the **autoindent** edit option is set, and the events described in 1. or 2. are performed, any <blank> characters at or after the cursor in the current line shall be discarded.

The ending margin shall be determined by the system or overridden by the user, as described for *COLUMNS* in in the ENVIRONMENT VARIABLES section and the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

wrapscan, ws

[Default *set*]

If **wrapscan** is set, searches (the *ex* **/** or **?** addresses, or open and visual mode **/**, **?**, **N**, and **n** commands) shall wrap around the beginning or end of the edit buffer; when unset, searches shall stop at the beginning or end of the edit buffer.

writeany, wa

[Default *unset*]

If **writeany** is set, some of the checks performed when executing the *ex* **write** commands shall be inhibited, as described in editor option **autowrite**.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *ex* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered, it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in **Command Line Parsing in ex** (on page 2573).

APPLICATION USAGE

If a SIGSEGV signal is received while *ex* is saving a file, the file might not be successfully saved.

The **next** command can accept more than one file, so usage such as:

```
next 'ls [abc]*'
```

is valid; it would not be valid for the **edit** or **read** commands, for example, because they expect only one file and unspecified results occur.

EXAMPLES

None.

RATIONALE

The *ex*/*vi* specification is based on the historical practice found in the 4 BSD and System V implementations of *ex* and *vi*. A freely redistributable implementation of *ex*/*vi*, which is tracking IEEE Std. 1003.1-200x fairly closely, and demonstrates the intended changes between historical implementations and IEEE Std. 1003.1-200x, may be obtained by anonymous FTP from:

```
ftp://ftp.rdg.opengroup/pub/mirrors/nvi
```

A *restricted editor* (both the historical *red* utility and modifications to *ex*) were considered and rejected for inclusion. Neither option provided the level of security that users might expect.

It is recognized that *ex* visual mode and related features would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing; thus, it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that an *ex* implementation should provide the full set of capabilities on all terminals capable of supporting them.

Options

The **–c** replacement for **+***command* was inspired by the **–e** option of *sed*. Historically, all such commands (see **edit** and **next** as well) were executed from the last line of the edit buffer. This meant, for example, that `"+/pattern"` would fail unless the **wrapscan** option was set. IEEE Std. 1003.1-200x requires conformance to historical practice. Historically, some implementations restricted the *ex* commands that could be listed as part of the command line arguments. For consistency, IEEE Std. 1003.1-200x does not permit these restrictions.

In historical implementations of the editor, the **–R** option (and the **readonly** edit option) only prevented overwriting of files; appending to files was still permitted, mapping loosely into the *csh* **noclobber** variable. Some implementations, however, have not followed this semantic, and **readonly** does not permit appending either. IEEE Std. 1003.1-200x follows the latter practice, believing that it is a more obvious and intuitive meaning of **readonly**.

The **–s** option suppresses all interactive user feedback and is useful for editing scripts in batch jobs. The list of specific effects is historical practice. The terminal type ‘‘incapable of supporting open and visual modes’’ has historically been named ‘‘dumb’’.

The **–t** option was required because the *ctags* utility appears in IEEE Std. 1003.1-200x and the option is available in all historical implementations of *ex*.

Historically, the *ex* and *vi* utilities accepted a **–x** option, which did encryption based on the algorithm found in the historical *crypt* utility. The **–x** option for encryption, and the associated *crypt* utility, were omitted because the algorithm used was not specifiable and the export control laws of some nations make it difficult to export cryptographic technology. In addition, it did not historically provide the level of security that users might expect.

Standard Input

An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically an *ex* command.

There was no maximum line length in historical implementations of *ex*. Specifically, as it was parsed in chunks, the addresses had a different maximum length than the file names. Further, the maximum line buffer size was declared as {BUFSIZ}, which was different lengths on different systems. This version selected the value of {LINE_MAX} to impose a reasonable restriction on portable usage of *ex* and to aid test suite writers in their development of realistic tests that exercise this limit.

Input Files

It was an explicit decision by the standard developers that a <newline> character be added to any file lacking one. It was believed that this feature of *ex* and *vi* was relied on by users in order to make text files lacking a trailing <newline> more portable. It is recognized that this will require a user-specified option or extension for implementations that permit *ex* and *vi* to edit files of type other than text if such files are not otherwise identified by the system. It was agreed that the ability to edit files of arbitrary type can be useful, but it was not considered necessary to mandate that an *ex* or *vi* implementation be required to handle files other than text files.

The paragraph in the INPUT FILES section, ‘‘By default, . . .’’, is intended to close a long-standing security problem in *ex* and *vi*, that of the ‘‘modeline’’ or ‘‘modelines’’ edit option. This feature allows any line in the first or last five lines of the file containing the strings `"ex:"` or `"vi:"` (and, apparently, `"ei:"` or `"vx:"`) to be a line containing editor commands, and *ex* interprets all the text up to the next `':'` or <newline> as a command. Consider the consequences, for example, of an unsuspecting user using *ex* or *vi* as the editor when replying to a mail message in which a line such as:

```
ex:! rm –rf :
```

appeared in the signature lines. The standard developers believed strongly that an editor should not by default interpret any lines of a file. Vendors are strongly urged to delete this feature from their implementations of *ex* and *vi*.

Asynchronous Events

The intention of the phrase ‘‘complete write’’ is that the entire edit buffer be written to stable storage. The note regarding temporary files is intended for implementations that use temporary files to back edit buffers unnamed by the user.

Historically, SIGQUIT was ignored by *ex*, but was the equivalent of the **Q** command in visual mode; that is, it exited visual mode and entered *ex* mode. IEEE Std. 1003.1-200x permits, but does not require, this behavior. Historically, SIGINT was often used by *vi* users to terminate text input mode (<control>-C is often easier to enter than <ESC>). Some implementations of *vi* alerted the terminal on this event, and some did not. IEEE Std. 1003.1-200x requires that SIGINT behave identically to <ESC>, and that the terminal not be alerted.

Historically, suspending the *ex* editor during text input mode was similar to SIGINT, as completed lines were retained, but any partial line discarded, and the editor returned to command mode. IEEE Std. 1003.1-200x is silent on this issue; implementations are encouraged to follow historical practice, where possible.

Historically, the *vi* editor did not treat SIGTSTP as an asynchronous event, and it was therefore impossible to suspend the editor in visual text input mode. There are two major reasons for this. The first is that SIGTSTP is a broadcast signal on UNIX systems, and the chain of events where the shell *exec*s an application that then *exec*s *vi* usually caused confusion for the terminal state if SIGTSTP was delivered to the process group in the default manner. The second was that most implementations of the UNIX *curses* package are not reentrant, and the receipt of SIGTSTP at the wrong time will cause them to crash. IEEE Std. 1003.1-200x is silent on this issue; implementations are encouraged to treat suspension as an asynchronous event if possible.

Historically, modifications to the edit buffer made before SIGINT interrupted an operation were retained; that is, anywhere from zero to all of the lines to be modified might have been modified by the time the SIGINT arrived. These changes were not discarded by the arrival of SIGINT. IEEE Std. 1003.1-200x permits this behavior, noting that the *undo* command is required to be able to undo these partially completed commands.

The action taken for signals other than SIGINT, SIGCONT, SIGHUP, and SIGTERM is unspecified because some implementations attempt to save the edit buffer in a useful state when other signals are received.

Standard Error

For *ex*/*vi*, diagnostic messages are those messages reported as a result of a failed attempt to invoke *ex* or *vi*, such as invalid options or insufficient resources, or an abnormal termination condition. Diagnostic messages should not be confused with the error messages generated by inappropriate or illegal user commands.

Initialization in ex and vi

If an *ex* command (other than **cd**, **chdir**, or **source**) has a file name argument, one or both of the alternate and current path names will be set. Informally, they are set as follows:

1. If the *ex* command is one that replaces the contents of the edit buffer, and it succeeds, the current path name will be set to the file name argument (the first file name argument in the case of the **next** command) and the alternate path name will be set to the previous current path name, if there was one.
2. In the case of the file read/write forms of the **read** and **write** commands, if there is no current path name, the current path name will be set to the file name argument.
3. Otherwise, the alternate path name will be set to the file name argument.

For example, **:edit foo** and **:recover foo**, when successful, set the current path name, and, if there was a previous current path name, the alternate path name. The commands **:write**, **!command**, and **:edit** set neither the current or alternate path names. If the **:edit foo** command were to fail for some reason, the alternate path name would be set. The **read** and **write** commands set the alternate path name to their *file* argument, unless the current path name is not set, in which case they set the current path name to their *file* arguments. The alternate path name was not historically set by the **:source** command. IEEE Std. 1003.1-200x requires conformance to historical practice. Implementations adding commands that take file names as arguments are encouraged to set the alternate path name as described here.

Historically, *ex* and *vi* read the **.exrc** file in the *$HOME* directory twice, if the editor was executed in the *$HOME* directory. IEEE Std. 1003.1-200x prohibits this behavior.

Historically, the 4 BSD *ex* and *vi* read the *$HOME* and local **.exrc** files if they were owned by the real ID of the user, or the **sourceany** option was set, regardless of other considerations. This was a security problem because it is possible to put normal UNIX system commands inside a **.exrc** file. IEEE Std. 1003.1-200x does not specify the **sourceany** option, and historical implementations are encouraged to delete it.

The **.exrc** files must be owned by the real ID of the user, and not writeable by anyone other than the owner. The appropriate privileges exception is intended to permit users to acquire special privileges, but continue to use the **.exrc** files in their home directories.

System V Release 3.2 and later *vi* implementations added the option **[no]exrc**. The behavior is that local **.exrc** files are read-only if the **exrc** option is set. The default for the **exrc** option was off, so by default, local **.exrc** files were not read. The problem this was intended to solve was that System V permitted users to give away files, so there is no possible ownership or writeability test to ensure that the file is safe. This is still a security problem on systems where users can give away files, but there is nothing additional that IEEE Std. 1003.1-200x can do. The implementation-defined exception is intended to permit groups to have local **.exrc** files that are shared by users, by creating pseudo-users to own the shared files.

IEEE Std. 1003.1-200x does not mention system-wide *ex* and *vi* start-up files. While they exist in several implementations of *ex* and *vi*, they are not present in any implementations considered historical practice by IEEE Std. 1003.1-200x. Implementations that have such files should use them only if they are owned by the real user ID or an appropriate user (for example, root on UNIX systems) and if they are not writeable by any user other than their owner. System-wide start-up files should be read before the *EXINIT* variable, **$HOME/.exrc** or local **.exrc** files are evaluated.

Historically, any *ex* command could be entered in the *EXINIT* variable or the **.exrc** file, although ones requiring that the edit buffer already contain lines of text generally caused historical implementations of the editor to drop core. IEEE Std. 1003.1-200x requires that any *ex* command

15437 be permitted in the *EXINIT* variable and **.exrc** files, for simplicity of specification and
15438 consistency, although many of them will obviously fail under many circumstances.

15439 The initialization of the contents of the edit buffer uses the phrase ''the effect shall be'' with
15440 regard to various *ex* commands. The intent of this phrase is that edit buffer contents loaded
15441 during the initialization phase not be lost; that is, loading the edit buffer should fail if the **.exrc**
15442 file read in the contents of a file and did not subsequently write the edit buffer. An additional
15443 intent of this phrase is to specify that the initial current line and column is set as specified for the
15444 individual *ex* commands.

15445 Historically, the **–t** option behaved as if the tag search were a **+***command*; that is, it was executed
15446 from the last line of the file specified by the tag. This resulted in the search failing if the pattern
15447 was a forward search pattern and the **wrapscan** edit option was not set. IEEE Std. 1003.1-200x
15448 does not permit this behavior, requiring that the search for the tag pattern be performed on the
15449 entire file, and, if not found, that the current line be set to a more reasonable location in the file.

15450 Historically, the empty edit buffer presented for editing when a file was not specified by the user
15451 was unnamed. This is permitted by IEEE Std. 1003.1-200x; however, implementations are
15452 encouraged to provide users a temporary file name for this buffer because it permits them the
15453 use of *ex* commands that use the current path name during temporary edit sessions.

15454 Historically, the file specified using the **–t** option was not part of the current argument list. This
15455 practice is permitted by IEEE Std. 1003.1-200x; however, implementations are encouraged to
15456 include its name in the current argument list for consistency.

15457 Historically, the **–c** command was generally not executed until a file that already exists was
15458 edited. IEEE Std. 1003.1-200x requires conformance to this historical practice. Commands that
15459 could cause the **–c** command to be executed include the *ex* commands **edit**, **next**, **recover**,
15460 **rewind**, and **tag**, and the *vi* commands <control>-^ and <control>-]. Historically, reading a file
15461 into an edit buffer did not cause the **–c** command to be executed (even though it might set the
15462 current path name) with the exception that it did cause the **–c** command to be executed if: the
15463 editor was in *ex* mode, the edit buffer had no current path name, the edit buffer was empty, and
15464 no read commands had yet been attempted. For consistency and simplicity of specification,
15465 IEEE Std. 1003.1-200x does not permit this behavior.

15466 Historically, the **–r** option was the same as a normal edit session if there was no recovery
15467 information available for the file. This allowed users to enter:

15468 `vi –r *.c`

15469 and recover whatever files were recoverable. In some implementations, recovery was attempted
15470 only on the first file named, and the file was not entered into the argument list; in others,
15471 recovery was attempted for each file named. In addition, some historical implementations
15472 ignored **–r** if **–t** was specified or did not support command line *file* arguments with the **–t** option.
15473 For consistency and simplicity of specification, IEEE Std. 1003.1-200x disallows these special
15474 cases, and requires that recovery be attempted the first time each file is edited.

15475 Historically, *vi* initialized the **‘** and **’** marks, but *ex* did not. This meant that if the first command
15476 in *ex* mode was **visual** or if an *ex* command was executed first (for example, *vi* +10 *file*), *vi* was
15477 entered without the marks being initialized. Because the standard developers believed the marks
15478 to be generally useful, and for consistency and simplicity of specification, IEEE Std. 1003.1-200x
15479 requires that they always be initialized if in open or visual mode, or if in *ex* mode and the edit
15480 buffer is not empty. Not initializing it in *ex* mode if the edit buffer is empty is historical practice;
15481 however, it has always been possible to set (and use) marks in empty edit buffers in open and
15482 visual mode edit sessions.

Addressing

Historically, *ex* and *vi* accepted the additional addressing forms '\/' and '\?'. They were equivalent to "//" and "??", respectively. They are not required by IEEE Std. 1003.1-200x, mostly because nobody can remember whether they ever did anything different historically.

Historically, *ex* and *vi* permitted an address of zero for several commands, and permitted the **%** address in empty files for others. For consistency, IEEE Std. 1003.1-200x requires support for the former in the few commands where it makes sense, and disallows it otherwise. In addition, because IEEE Std. 1003.1-200x requires that **%** be logically equivalent to "1,$", it is also supported where it makes sense and disallowed otherwise.

Historically, the **%** address could not be followed by further addresses. For consistency and simplicity of specification, IEEE Std. 1003.1-200x requires that additional addresses be supported.

All of the following are valid *addresses*:

+++ Three lines after the current line.

/*re*/– One line before the next occurrence of *re*.

–2 Two lines before the current line.

3 ––– 2 Line one (note intermediate negative address).

1 2 3 Line six.

Any number of addresses can be provided to commands taking addresses; for example, "1,2,3,4,5p" prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command **3;/foo/;+2print** will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address **3;** must be evaluated before being discarded because the search origin for the **/foo/** command depends on this.

Historically, values could be added to addresses by including them after one or more <blank> characters; for example, **3 – 5p** wrote the seventh line of the file, and **/foo/ 5** was the same as **/foo/+5**. However, only absolute values could be added; for example, **5 /foo/** was an error. IEEE Std. 1003.1-200x requires conformance to historical practice. Address offsets are separately specified from addresses because they could historically be provided to visual mode search commands.

Historically, any missing addresses defaulted to the current line. This was true for leading and trailing comma-delimited addresses, and for trailing semicolon-delimited addresses. For consistency, IEEE Std. 1003.1-200x requires it for leading semicolon addresses as well.

Historically, *ex* and *vi* accepted the '^' character as both an address and as a flag offset for commands. In both cases it was identical to the '–' character. IEEE Std. 1003.1-200x does not require or prohibit this behavior.

Historically, the enhancements to basic regular expressions could be used in addressing; for example, '~', '\<', and '\>'. IEEE Std. 1003.1-200x requires conformance to historical practice; that is, that regular expression usage be consistent, and that regular expression enhancements be supported wherever regular expressions are used.

15524 **Command Line Parsing in ex**

15525 Historical *ex* command parsing was even more complex than that described here.
15526 IEEE Std. 1003.1-200x requires the subset of the command parsing that the standard developers
15527 believed was documented and that users could reasonably be expected to use in a portable
15528 fashion, and that was historically consistent between implementations. (The discarded
15529 functionality is obscure, at best.) Historical implementations will require changes in order to
15530 comply with IEEE Std. 1003.1-200x; however, users are not expected to notice any of these
15531 changes. Most of the complexity in *ex* parsing is to handle three special termination cases:

15532 1. The **!**, **global**, **v**, and the filter versions of the **read** and **write** commands are delimited by
15533 <newline> characters (they can contain vertical-line characters that are usually shell pipes).

15534 2. The **ex**, **edit**, **next**, and **visual** in open and visual mode commands all take *ex* commands,
15535 optionally containing vertical-line characters, as their first arguments.

15536 3. The **s** command takes a regular expression as its first argument, and uses the delimiting
15537 characters to delimit the command.

15538 Historically, vertical-line characters in the **+***command* argument of the **ex**, **edit**, **next**, **vi**, and
15539 **visual** commands, and in the *pattern* and *replacement* parts of the **s** command, did not delimit the
15540 command, and in the filter cases for **read** and **write**, and the **!**, **global**, and **v** commands, they did
15541 not delimit the command at all. For example, the following commands are all valid:

```
15542 :edit +25 | s/abc/ABC/ file.c
15543 :s/ | /PIPE/
15544 :read !spell % | columnate
15545 :global/pattern/p | l
15546 :s/a/b/ | s/c/d | set
```

15547 Historically, empty or <blank> filled lines in **.exrc** files and **source**d files (as well as *EXINIT* |
15548 variables and *ex* command scripts) were treated as default commands; that is, **print** commands.
15549 IEEE Std. 1003.1-200x specifically requires that they be ignored when encountered in **.exrc** and
15550 **source**d files to eliminate a common source of new user error.

15551 Historically, *ex* commands with multiple adjacent (or <blank>-separated) vertical lines were
15552 handled oddly when executed from *ex* mode. For example, the command **|||** <carriage-return>,
15553 when the cursor was on line 1, displayed lines 2, 3, and 5 of the file. In addition, the command **|**
15554 would only display the line after the next line, instead of the next two lines. The former worked
15555 more logically when executed from *vi* mode, and displayed lines 2, 3, and 4.
15556 IEEE Std. 1003.1-200x requires the *vi* behavior; that is, a single default command and line
15557 number increment for each command separator, and trailing <newline> characters after
15558 vertical-line separators are discarded.

15559 Historically, *ex* permitted a single extra colon as a leading command character; for example,
15560 **:g/pattern/:p** was a valid command. IEEE Std. 1003.1-200x generalizes this to require that any
15561 number of leading colon characters be stripped.

15562 Historically, any prefix of the **delete** command could be followed without intervening <blank>
15563 characters by a flag character because in the command **d p**, *p* is interpreted as the buffer *p*.
15564 IEEE Std. 1003.1-200x requires conformance to historical practice.

15565 Historically, the **k** command could be followed by the mark name without intervening <blank>
15566 characters. IEEE Std. 1003.1-200x requires conformance to historical practice.

15567 Historically, the **s** command could be immediately followed by flag and option characters; for
15568 example, **s/e/E/|s|sgc3p** was a valid command. However, flag characters could not stand alone;
15569 for example, the commands **sp** and **s l** would fail, while the command **sgp** and **s gl** would

15570 succeed. (Obviously, the '#' flag character was used as a delimiter character if it followed the
15571 command.) Another issue was that option characters had to precede flag characters even when
15572 the command was fully specified; for example, the command **s/e/E/pg** would fail, while the
15573 command **s/e/E/gp** would succeed. IEEE Std. 1003.1-200x requires conformance to historical
15574 practice.

15575 Historically, the first command name that had a prefix matching the input from the user was the
15576 executed command; for example, **ve**, **ver**, and **vers** all executed the **version** command.
15577 Commands were in a specific order, however, so that **a** matched **append**, not **abbreviate**.
15578 IEEE Std. 1003.1-200x requires conformance to historical practice. The restriction on command
15579 search order for implementations with extensions is to avoid the addition of commands such
15580 that the historical prefixes would fail to work portably.

15581 Historical implementations of *ex* and *vi* did not correctly handle multiple *ex* commands,
15582 separated by vertical-line characters, that entered or exited visual mode or the editor. Because
15583 implementations of *vi* exist that do not exhibit this failure mode, IEEE Std. 1003.1-200x does not
15584 permit it.

15585 The requirement that alphabetic command names consist of all following alphabetic characters
15586 up to the next non-alphabetic character means that alphabetic command names must be
15587 separated from their arguments by one or more non-alphabetic characters, normally a <blank>
15588 or '!' character, except as specified for the exceptions, the **delete**, **k**, and **s** commands.

15589 Historically, the repeated execution of the *ex* default **print** commands (<control>-D, *eof*,
15590 <newline>, <carriage-return>) erased any prompting character and displayed the next lines
15591 without scrolling the terminal; that is, immediately below any previously displayed lines. This
15592 provided a cleaner presentation of the lines in the file for the user. IEEE Std. 1003.1-200x does not
15593 require this behavior because it may be impossible in some situations; however,
15594 implementations are strongly encouraged to provide this semantic if possible.

15595 Historically, it was possible to change files in the middle of a command, and have the rest of the
15596 command executed in the new file; for example:

15597 ```
:edit +25 file.c | s/abc/ABC/ | 1
```

15598 was a valid command, and the substitution was attempted in the newly edited file.
15599 IEEE Std. 1003.1-200x requires conformance to historical practice. The following commands are
15600 examples that exercise the *ex* parser:

15601 ```
echo 'foo | bar' > file1; echo 'foo/bar' > file2;
15602 vi
15603 :edit +1 | s/|/PIPE/ | w file1 | e file2 | 1 | s/\//SLASH/ | wq
```

15604 Historically, there was no protection in editor implementations to avoid *ex* **global**, **v**, **@**, or *****
15605 commands changing edit buffers during execution of their associated commands. Because this
15606 would almost invariably result in catastrophic failure of the editor, and implementations exist
15607 that do exhibit these problems, IEEE Std. 1003.1-200x requires that changing the edit buffer
15608 during a **global** or **v** command, or during a **@** or ***** command for which there will be more than a
15609 single execution, be an error. Implementations supporting multiple edit buffers simultaneously
15610 are strongly encouraged to apply the same semantics to switching between buffers as well.

15611 The *ex* command quoting required by IEEE Std. 1003.1-200x is a superset of the quoting in
15612 historical implementations of the editor. For example, it was not historically possible to escape a
15613 <blank> character in a file name; for example, **:edit foo\\\ bar** would report that too many file
15614 names had been entered for the edit command, and there was no method of escaping a <blank>
15615 in the first argument of an **edit**, **ex**, **next**, or **visual** command at all. IEEE Std. 1003.1-200x extends
15616 historical practice, requiring that quoting behavior be made consistent across all *ex* commands,

except for the **map**, **unmap**, **abbreviate**, and **unabbreviate** commands, which historically used <control>-V instead of backslashes for quoting. For those four commands, IEEE Std. 1003.1-200x requires conformance to historical practice.

Backslash quoting in *ex* is non-intuitive. Backslash escapes are ignored unless they escape a special character; for example, when performing *file* argument expansion, the string `"\\%"` is equivalent to `'\%'`, not `"\<current path name>"`. This can be confusing for users because backslash is usually one of the characters that causes shell expansion to be performed, and therefore shell quoting rules must be taken into consideration. Generally, quoting characters are only considered if they escape a special character, and a quoting character must be provided for each layer of parsing for which the character is special. As another example, only a single backslash is necessary for the `'\l'` sequence in substitute replacement patterns, because the character `'l'` is not special to any parsing layer above it.

<control>-V quoting in *ex* is slightly different from backslash quoting. In the four commands where <control>-V quoting applies (**abbreviate**, **unabbreviate**, **map**, and **unmap**), any character may be escaped by a <control>-V whether it would have a special meaning or not. IEEE Std. 1003.1-200x requires conformance to historical practice.

Historical implementations of the editor did not require delimiters within character classes to be escaped; for example, the command **:s/[/]//** on the string `"xxx/yyy"` would delete the `'//'` from the string. IEEE Std. 1003.1-200x disallows this historical practice for consistency and because it places a large burden on implementations by requiring that knowledge of regular expressions be built into the editor parser.

Historically, quoting <newline> characters in *ex* commands was handled inconsistently. In most cases, the <newline> always terminated the command, regardless of any preceding escape character, because backslash characters did not escape <newline> characters for most *ex* commands. However, some *ex* commands (for example, **s**, **map**, and **abbreviation**) permitted <newline> characters to be escaped (although in the case of **map** and **abbreviation**, <control>-V characters escaped them instead of backslashes). This was true in not only the command line, but also **.exrc** and **source**d files. For example, the command:

```
map = foo<control-V><newline>bar
```

would succeed, although it was sometimes difficult to get the <control>-V and the inserted <newline> passed to the *ex* parser. For consistency and simplicity of specification, IEEE Std. 1003.1-200x requires that it be possible to escape <newline> characters in *ex* commands at all times, using backslashes for most *ex* commands, and using <control>-V characters for the **map** and **abbreviation** commands. For example, the command **print**<newline>**list** is required to be parsed as the single command **print**<newline>**list**. While this differs from historical practice, IEEE Std. 1003.1-200x developers believed it unlikely that any script or user depended on the historical behavior.

Historically, an error in a command specified using the **–c** option did not cause the rest of the **–c** commands to be discarded. IEEE Std. 1003.1-200x disallows this for consistency with mapped keys, the **@**, **global**, **source**, and **v** commands, the *EXINIT* environment variable, and the **.exrc** files.

Input Editing in ex

One of the common uses of the historical *ex* editor is over slow network connections. Editors that run in canonical mode can require far less traffic to and from, and far less processing on, the host machine, as well as more easily supporting block-mode terminals. For these reasons, IEEE Std. 1003.1-200x requires that *ex* be implemented using canonical mode input processing, as was done historically.

IEEE Std. 1003.1-200x does not require the historical 4 BSD input editing characters ‘‘word erase’’ or ‘‘literal next’’. For this reason, it is unspecified how they are handled by *ex*, although they must have the required effect. Implementations that resolve them after the line has been ended using a <newline> or <control>-M character, and implementations that rely on the underlying system terminal support for this processing, are both conforming. Implementations are strongly urged to use the underlying system functionality, if at all possible, for compatibility with other system text input interfaces.

Historically, when the *eof* character was used to decrement the **autoindent** level, the cursor moved to display the new end of the **autoindent** characters, but did not move the cursor to a new line, nor did it erase the <control>-D character from the line. IEEE Std. 1003.1-200x does not specify that the cursor remain on the same line or that the rest of the line is erased; however, implementations are strongly encouraged to provide the best possible user interface; that is, the cursor should remain on the same line, and any <control>-D character on the line should be erased.

IEEE Std. 1003.1-200x does not require the historical 4 BSD input editing character ‘‘reprint’’, traditionally <control>-R, which redisplayed the current input from the user. For this reason, and because the functionality cannot be implemented after the line has been terminated by the user, IEEE Std. 1003.1-200x makes no requirements about this functionality. Implementations are strongly urged to make this historical functionality available, if possible.

Historically, <control>-Q did not perform a literal next function in *ex*, as it did in *vi*. IEEE Std. 1003.1-200x requires conformance to historical practice to avoid breaking historical *ex* scripts and **.exrc** files.

eof

Whether the *eof* character immediately modifies the **autoindent** characters in the prompt is left unspecified so that implementations can conform in the presence of systems that do not support this functionality. Implementations are encouraged to modify the line and redisplay it immediately, if possible.

The specification of the handling of the *eof* character differs from historical practice only in that *eof* characters are not discarded if they follow normal characters in the text input. Historically, they were always discarded.

Command Descriptions in ex

Historically, several commands (for example, **global**, **v**, **visual**, **s**, **write**, **wq**, **yank**, **!**, **<**, **>**, **&**, and **~**) were executable in empty files (that is, the default address(es) were 0), or permitted explicit addresses of 0 (for example, 0 was a valid address, or 0,0 was a valid range). Addresses of 0, or command execution in an empty file, make sense only for commands that add new text to the edit buffer or write commands (because users may wish to write empty files). IEEE Std. 1003.1-200x requires this behavior for such commands and disallows it otherwise, for consistency and simplicity of specification.

A count to an *ex* command has been historically corrected to be no greater than the last line in a file; for example, in a five-line file, the command **1,6print** would fail, but the command **1print300**

would succeed. IEEE Std. 1003.1-200x requires conformance to historical practice.

Historically, the use of flags in *ex* commands could be obscure. General historical practice was as described by IEEE Std. 1003.1-200x, but there were some special cases. For example, the **list**, **number**, and **print** commands ignored trailing address offsets; for example, **3p +++#** would display line 3, and 3 would be the current line after the execution of the command. The **open** and **visual** commands ignored both the trailing offsets and the trailing flags. Also, flags specified to the **open** and **visual** commands interacted badly with the **list** edit option, and setting and then unsetting it during the open/visual session would cause *vi* to stop displaying lines in the specified format. For consistency and simplicity of specification, IEEE Std. 1003.1-200x does not permit any of these exceptions to the general rule.

IEEE Std. 1003.1-200x uses the word *copy* in several places when discussing buffers. This is not intended to imply implementation.

Historically, *ex* users could not specify numeric buffers because of the ambiguity this would cause; for example, in the command **3 delete 2**, it is unclear whether 2 is a buffer name or a *count*. IEEE Std. 1003.1-200x requires conformance to historical practice by default, but does not preclude extensions.

Historically, the contents of the unnamed buffer were frequently discarded after commands that did not explicitly affect it; for example, when using the **edit** command to switch files. For consistency and simplicity of specification, IEEE Std. 1003.1-200x does not permit this behavior.

The *ex* utility did not historically have access to the numeric buffers, and, furthermore, deleting lines in *ex* did not modify their contents. For example, if, after doing a delete in *vi*, the user switched to *ex*, did another delete, and then switched back to *vi*, the contents of the numeric buffers would not have changed. IEEE Std. 1003.1-200x requires conformance to historical practice. Numeric buffers are described in the *ex* utility in order to confine the description of buffers to a single location in IEEE Std. 1003.1-200x.

The metacharacters that trigger shell expansion in *file* arguments match historical practice, as does the method for doing shell expansion. Implementations wishing to provide users with the flexibility to alter the set of metacharacters are encouraged to provide a **shellmeta** string edit option.

Historically, *ex* commands executed from *vi* refreshed the screen when it did not strictly need to do so; for example, **:!date > /dev/null** does not require a screen refresh because the output of the UNIX *date* command requires only a single line of the screen. IEEE Std. 1003.1-200x requires that the screen be refreshed if it has been overwritten, but makes no requirements as to how an implementation should make that determination. Implementations may prompt and refresh the screen regardless.

Abbreviate

Historical practice was that characters that were entered as part of an abbreviation replacement were subject to **map** expansions, the **showmatch** edit option, further abbreviation expansions, and so on; that is, they were logically pushed onto the terminal input queue, and were not a simple replacement. IEEE Std. 1003.1-200x requires conformance to historical practice. Historical practice was that whenever a non-word character (that had not been escaped by a <control>-V) was entered after a word character, *vi* would check for abbreviations. The check was based on the type of the character entered before the word character of the word/non-word pair that triggered the check. The word character of the word/non-word pair that triggered the check and all characters entered before the trigger pair that were of that type were included in the check, with the exception of <blank> characters, which always delimited the abbreviation.

This means that, for the abbreviation to work, the *lhs* must end with a word character, there can be no transitions from word to non-word characters (or *vice versar*) other than between the last and next-to-last characters in the *lhs*, and there can be no <blank> characters in the *lhs*. In addition, because of the historical quoting rules, it was impossible to enter a literal <control>-V in the *lhs*. IEEE Std. 1003.1-200x requires conformance to historical practice. Historical implementations did not inform users when abbreviations that could never be used were entered; implementations are strongly encouraged to do so.

For example, the following abbreviations will work:

```
:ab (p  REPLACE
:ab p   REPLACE
:ab ((p REPLACE
```

The following abbreviations will not work:

```
:ab (   REPLACE
:ab (pp REPLACE
```

Historical practice is that words on the *vi* colon command line were subject to abbreviation expansion, including the arguments to the **abbrev** (and more interestingly) the **unabbrev** command. Because there are implementations that do not do abbreviation expansion for the first argument to those commands, this is permitted, but not required, by IEEE Std. 1003.1-200x. However, the following sequence:

```
:ab foo bar
:ab foo baz
```

resulted in the addition of an abbreviation of `"baz"` for the string `"bar"` in historical *ex*/*vi*, and the sequence:

```
:ab foo1 bar
:ab foo2 bar
:unabbreviate foo2
```

deleted the abbreviation `"foo1"`, not `"foo2"`. These behaviors are not permitted by IEEE Std. 1003.1-200x because they clearly violate the expectations of the user.

It was historical practice that <control>-V, not backslash, characters be interpreted as escaping subsequent characters in the **abbreviate** command. IEEE Std. 1003.1-200x requires conformance to historical practice; however, it should be noted that an abbreviation containing a <blank> will never work.

Append

Historically, any text following a vertical-line command separator after an **append**, **change**, or **insert** command became part of the insert text. For example, in the command:

```
:g/pattern/append|stuff1
```

a line containing the text `"stuff1"` would be appended to each line matching pattern. It was also historically valid to enter:

```
:append|stuff1
stuff2
.
```

and the text on the *ex* command line would be appended along with the text inserted after it. There was an historical bug, however, that the user had to enter two terminating lines (the `'.'` lines) to terminate text input mode in this case. IEEE Std. 1003.1-200x requires conformance to

15794 historical practice, but disallows the historical need for multiple terminating lines.

15795 **Change**

15796 See the RATIONALE for the **append** command. Historical practice for cursor positioning after
15797 the change command when no text is input, is as described in IEEE Std. 1003.1-200x. However,
15798 one System V implementation is known to have been modified such that the cursor is positioned
15799 on the first address specified, and not on the line before the first address. IEEE Std. 1003.1-200x
15800 disallows this modification for consistency.

15801 Historically, the **change** command did not support buffer arguments, although some
15802 implementations allow the specification of an optional buffer. This behavior is neither required
15803 nor disallowed by IEEE Std. 1003.1-200x.

15804 **Change Directory**

15805 A common extension in *ex* implementations is to use the elements of a **cdpath** edit option as
15806 prefix directories for *path* arguments to **chdir** that are relative path names and that do not have
15807 `'.'` or `".."` as their first component. Elements in the **cdpath** edit option are colon-separated.
15808 The initial value of the **cdpath** edit option is the value of the shell *CDPATH* environment
15809 variable. This feature was not included in IEEE Std. 1003.1-200x because it does not exist in any
15810 of the implementations considered historical practice.

15811 **Copy**

15812 Historical implementations of *ex* permitted copies to lines inside of the specified range; for
15813 example, **:2,5copy3** was a valid command. IEEE Std. 1003.1-200x requires conformance to
15814 historical practice.

15815 **Delete**

15816 IEEE Std. 1003.1-200x requires support for the historical parsing of a **delete** command followed
15817 by flags, without any intervening <blank> characters. For example:

15818 **1dp** Deletes the first line and prints the line that was second.

15819 **1delep** As for **1dp**.

15820 **1d** Deletes the first line, saving it in buffer *p*.

15821 **1d p1l** (Pee-one-ell.) Deletes the first line, saving it in buffer *p*, and listing the line that was
15822 second.

15823 **Edit**

15824 Historically, any *ex* command could be entered as a **+***command* argument to the **edit** command,
15825 although some (for example, **insert** and **append**) were known to confuse historical
15826 implementations. For consistency and simplicity of specification, IEEE Std. 1003.1-200x requires
15827 that any command be supported as an argument to the **edit** command.

15828 Historically, the command argument was executed with the current line set to the last line of the
15829 file, regardless of whether the **edit** command was executed from visual mode or not.
15830 IEEE Std. 1003.1-200x requires conformance to historical practice.

15831 Historically, the **+***command* specified to the **edit** and **next** commands was delimited by the first
15832 <blank> character, and there was no way to quote them. For consistency, IEEE Std. 1003.1-200x
15833 requires that the usual *ex* backslash quoting be provided.

Historically, specifying the **+***command* argument to the edit command required a file name to be specified as well; for example, **:edit +100** would always fail. For consistency and simplicity of specification, IEEE Std. 1003.1-200x does not permit this usage to fail for that reason.

Historically, only the cursor position of the last file edited was remembered by the editor. IEEE Std. 1003.1-200x requires that this be supported; however, implementations are permitted to remember and restore the cursor position for any file previously edited.

File

Historical versions of the *ex* editor **file** command displayed a current line and number of lines in the edit buffer of 0 when the file was empty, while the *vi* <control>-G command displayed a current line and number of lines in the edit buffer of 1 in the same situation. IEEE Std. 1003.1-200x does not permit this discrepancy, instead requiring that a message be displayed indicating that the file is empty.

Global

The two-pass operation of the **global** and **v** commands is not intended to imply implementation, only the required result of the operation.

The current line and column are set as specified for the individual *ex* commands. This requirement is cumulative; that is, the current line and column must track across all the commands executed by the **global** or **v** commands.

Insert

See the RATIONALE for the **append** command.

Historically, **insert** could not be used with an address of zero; that is, not when the edit buffer was empty. IEEE Std. 1003.1-200x requires that this command behave consistently with the **append** command.

Join

The action of the **join** command in relation to the special characters is only defined for the POSIX locale because the correct amount of white space after a period varies; in Japanese none is required, in French only a single space, and so on.

List

The historical output of the **list** command was potentially ambiguous. The standard developers believed correcting this to be more important than adhering to historical practice, and IEEE Std. 1003.1-200x requires unambiguous output.

Map

Historically, command mode maps only applied to command names; for example, if the character `'x'` was mapped to `'y'`, the command **fx** searched for the `'x'` character, not the `'y'` character. IEEE Std. 1003.1-200x requires this behavior. Historically, entering <control>-V as the first character of a *vi* command was an error. Several implementations have extended the semantics of *vi* such that <control>-V means that the subsequent command character is not mapped. This is permitted, but not required, by IEEE Std. 1003.1-200x. Regardless, using <control>-V to escape the second or later character in a sequence of characters that might match a **map** command, or any character in text input mode, is historical practice, and stops the entered keys from matching a map. IEEE Std. 1003.1-200x requires conformance to historical practice.

Historical implementations permitted digits to be used as a **map** command *lhs*, but then ignored the map. IEEE Std. 1003.1-200x requires that the mapped digits not be ignored.

The historical implementation of the **map** command did not permit **map** commands that were more than a single character in length if the first character was printable. This behavior is permitted, but not required, by IEEE Std. 1003.1-200x.

Historically, mapped characters were remapped unless the **remap** edit option was not set, or the prefix of the mapped characters matched the mapping characters; for example, in the **map**:

```
:map ab abcd
```

the characters "ab" were used as is and were not remapped, but the characters "cd" were mapped if appropriate. This can cause infinite loops in the *vi* mapping mechanisms. IEEE Std. 1003.1-200x requires conformance to historical practice, and that such loops be interruptible.

Text input maps had the same problems with expanding the *lhs* for the *ex* **map!** and **unmap!** command as did the *ex* **abbreviate** and **unabbreviate** commands. See the RATIONALE for the *ex* **abbreviate** command. IEEE Std. 1003.1-200x requires similar modification of some historical practice for the **map** and **unmap** commands, as described for the **abbreviate** and **unabbreviate** commands.

Historically, **map**s that were subsets of other **map**s behaved differently depending on the order in which they were defined. For example:

```
:map! ab     short
:map! abc    long
```

would always translate the characters "ab" to "short", regardless of how fast the characters "abc" were entered. If the entry order was reversed:

```
:map! abc    long
:map! ab     short
```

the characters "ab" would cause the editor to pause, waiting for the completing 'c' character, and the characters might never be mapped to "short". For consistency and simplicity of specification, IEEE Std. 1003.1-200x requires that the shortest match be used at all times.

The length of time the editor spends waiting for the characters to complete the *lhs* is unspecified because the timing capabilities of systems are often inexact and variable, and it may depend on other factors such as the speed of the connection. The time should be long enough for the user to be able to complete the sequence, but not long enough for the user to have to wait. Some implementations of *vi* have added a **keytime** option, which permits users to set the number of 0,1 seconds the editor waits for the completing characters. Because mapped terminal function and cursor keys tend to start with an <ESC> character, and <ESC> is the key ending *vi* text input mode, **map**s starting with <ESC> characters are generally exempted from this timeout period, or, at least timed out differently.

Mark

Historically, users were able to set the ‘‘previous context’’ marks explicitly. In addition, the *ex* commands **’’** and **’‘** and the *vi* commands **’’**, **“**, **‘’**, and **’‘** all referred to the same mark. In addition, the previous context marks were not set if the command, with which the address setting the mark was associated, failed. IEEE Std. 1003.1-200x requires conformance to historical practice. Historically, if marked lines were deleted, the mark was also deleted, but would reappear if the change was undone. IEEE Std. 1003.1-200x requires conformance to historical practice.

15919 The description of the special events that set the ‘ and ’ marks matches historical practice. For
15920 example, historically the command **/a/,/b/** did not set the ‘ and ’ marks, but the command
15921 **/a/,/b/delete** did.

15922 **Next**

15923 Historically, any *ex* command could be entered as a **+***command* argument to the **next** command,
15924 although some (for example, **insert** and **append**) were known to confuse historical
15925 implementations. IEEE Std. 1003.1-200x requires that any command be permitted and that it
15926 behave as specified. The **next** command can accept more than one file, so usage such as:

15927 `next ‘ls [abc] ‘`

15928 is valid; it need not be valid for the **edit** or **read** commands, for example, because they expect
15929 only one file name.

15930 Historically, the **next** command behaved differently from the **:rewind** command in that it
15931 ignored the force flag if the **autowrite** flag was set. For consistency, IEEE Std. 1003.1-200x does
15932 not permit this behavior.

15933 Historically, the **next** command positioned the cursor as if the file had never been edited before,
15934 regardless. IEEE Std. 1003.1-200x does not permit this behavior, for consistency with the **edit**
15935 command.

15936 Implementations wanting to provide a counterpart to the **next** command that edited the
15937 previous file have used the command **prev[ious],** which takes no *file* argument.
15938 IEEE Std. 1003.1-200x does not require this command.

15939 **Open**

15940 Historically, the **open** command would fail if the **open** edit option was not set.
15941 IEEE Std. 1003.1-200x does not mention the **open** edit option and does not require this behavior.
15942 Some historical implementations do not permit entering open mode from open or visual mode,
15943 only from *ex* mode. For consistency, IEEE Std. 1003.1-200x does not permit this behavior.

15944 Historically, entering open mode from the command line (that is, *vi* **+open**) resulted in
15945 anomalous behaviors; for example, the *ex* file and *set* commands, and the *vi* command
15946 <control>-G did not work. For consistency, IEEE Std. 1003.1-200x does not permit this behavior.

15947 Historically, the **open** command only permitted `'/'` characters to be used as the search pattern
15948 delimiter. For consistency, IEEE Std. 1003.1-200x requires that the search delimiters used by the
15949 **s**, **global**, and **v** commands be accepted as well.

15950 **Preserve**

15951 The **preserve** command does not historically cause the file to be considered unmodified for the
15952 purposes of future commands that may exit the editor. IEEE Std. 1003.1-200x requires
15953 conformance to historical practice.

15954 Historical documentation stated that mail was not sent to the user when preserve was executed;
15955 however, historical implementations did send mail in this case. IEEE Std. 1003.1-200x requires
15956 conformance to the historical implementations.

15957 **Print**

15958 The writing of NUL by the **print** command is not specified as a special case because the standard
15959 developers did not want to require *ex* to support NUL characters. Historically, characters were
15960 displayed using the ARPA standard mappings, which are as follows:

15961 1. Printable characters are left alone.

15962 2. Control characters less than \177 are represented as `'^'` followed by the character offset
15963 from the `'@'` character in the ASCII map; for example, \007 is represented as `'^G'`.

15964 3. \177 is represented as `'^'` followed by `'?'`.

15965 The display of characters having their eighth bit set was less standard. Existing implementations
15966 use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed bytes that had their
15967 eighth bit set as the two characters `"M-"` followed by the seven-bit display as described above.)
15968 The latter probably has the best claim to historical practice because it was used for the **–v** option
15969 of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

15970 No specific display format is required by IEEE Std. 1003.1-200x.

15971 Explicit dependence on the ASCII character set has been avoided where possible, hence the use |
15972 of the phrase an ‘‘implementation-defined multi-character sequence’’ for the display of non- |
15973 printable characters in preference to the historical usage of, for instance, `"^I"` for the <tab>
15974 character. Implementations are encouraged to conform to historical practice in the absence of
15975 any strong reason to diverge.

15976 Historically, all *ex* commands beginning with the letter `'p'` could be entered using capitalized
15977 versions of the commands; for example, **P[rint]**, **Pre[serve]**, and **Pu[t]** were all valid command
15978 names. IEEE Std. 1003.1-200x permits, but does not require, this historical practice because
15979 capital forms of the commands are used by some implementations for other purposes.

15980 **Put**

15981 Historically, an *ex* **put** command, executed from open or visual mode, was the same as the open
15982 or visual mode **P** command, if the buffer was named and was cut in character mode, and the
15983 same as the **p** command if the buffer was named and cut in line mode. If the unnamed buffer
15984 was the source of the text, the entire line from which the text was taken was usually **put**, and the
15985 buffer was handled as if in line mode, but it was possible to get extremely anomalous behavior.
15986 In addition, using the **Q** command to switch into *ex* mode, and then doing a **put** often resulted in
15987 errors as well, such as appending text that was unrelated to the (supposed) contents of the
15988 buffer. For consistency and simplicity of specification, IEEE Std. 1003.1-200x does not permit
15989 these behaviors. All *ex* **put** commands are required to operate in line mode, and the contents of
15990 the buffers are not altered by changing the mode of the editor.

15991 **Read**

15992 Historically, an *ex* **read** command executed from open or visual mode, executed in an empty file,
15993 left an empty line as the first line of the file. For consistency and simplicity of specification,
15994 IEEE Std. 1003.1-200x does not permit this behavior. Historically, a **read** in open or visual mode
15995 from a program left the cursor at the last line read in, not the first. For consistency,
15996 IEEE Std. 1003.1-200x does not permit this behavior.

15997 Historical implementations of *ex* were unable to undo **read** commands that read from the output
15998 of a program. For consistency, IEEE Std. 1003.1-200x does not permit this behavior.

15999 Historically, the *ex* and *vi* message after a successful **read** or **write** command specified
16000 ‘‘characters’’, not ‘‘bytes’’. IEEE Std. 1003.1-200x requires that the number of bytes be displayed,

16001 not the number of characters, because it may be difficult in multi-byte implementations to
16002 determine the number of characters read. Implementations are encouraged to clarify the
16003 message displayed to the user.

16004 Historically, reads were not permitted on files other than type regular, except that FIFO files
16005 could be read (probably only because they did not exist when *ex* and *vi* were originally written).
16006 Because the historical *ex* evaluated **read!** and **read !** equivalently, there can be no optional way
16007 to force the read. IEEE Std. 1003.1-200x permits, but does not require, this behavior.

16008 **Recover**

16009 Some historical implementations of the editor permitted users to recover the edit buffer contents
16010 from a previous edit session, and then exit without saving those contents (or explicitly
16011 discarding them). The intent of IEEE Std. 1003.1-200x in requiring that the edit buffer be treated
16012 as already modified is to prevent this user error.

16013 **Rewind**

16014 Historical implementations supported the **rewind** command when the user was editing the first
16015 file in the list; that is, the file that the **rewind** command would edit. IEEE Std. 1003.1-200x
16016 requires conformance to historical practice.

16017 **Substitute**

16018 Historically, *ex* accepted an **r** option to the **s** command. The effect of the **r** option was to use the
16019 last regular expression used in any command as the pattern, the same as the **~** command. The **r**
16020 option is not required by IEEE Std. 1003.1-200x. Historically, the **c** and **g** options were toggled;
16021 for example, the command **:s/abc/def/** was the same as **s/abc/def/ccccgggg**. For simplicity of
16022 specification, IEEE Std. 1003.1-200x does not permit this behavior.

16023 The tilde command is often used to replace the last search RE. For example, in the sequence:

```
16024 s/red/blue/
16025 /green
16026 ~
```

16027 the **~** command is equivalent to:

```
16028 s/green/blue/
```

16029 Historically, *ex* accepted all of the following forms:

```
16030 s/abc/def/
16031 s/abc/def
16032 s/abc/
16033 s/abc
```

16034 IEEE Std. 1003.1-200x requires conformance to this historical practice.

16035 The **s** command presumes that the '^' character only occupies a single column in the display.
16036 Much of the *ex* and *vi* specification presumes that the <space> character only occupies a single
16037 column in the display. There are no known character sets for which this is not true.

16038 Historically, the final column position for the substitute commands was based on previous
16039 column movements; a search for a pattern followed by a substitution would leave the column
16040 position unchanged, while a 0 command followed by a substitution would change the column
16041 position to the first non-<blank>. For consistency and simplicity of specification,
16042 IEEE Std. 1003.1-200x requires that the final column position always be set to the first non-
16043 <blank>.

16044 **Set**

16045 Historical implementations redisplayed all of the options for each occurrence of the **all** keyword.
16046 IEEE Std. 1003.1-200x permits, but does not require, this behavior.

16047 **Tag**

16048 No requirement is made as to where *ex* and *vi* shall look for the file referenced by the tag entry.
16049 Historical practice has been to look for the path found in the **tags** file, based on the current
16050 directory. A useful extension found in some implementations is to look based on the directory
16051 containing the tags file that held the entry, as well. No requirement is made as to which
16052 reference for the tag in the tags file is used. This is deliberate, in order to permit extensions such
16053 as multiple entries in a tags file for a tag.

16054 Because users often specify many different tags files, some of which need not be relevant or exist
16055 at any particular time, IEEE Std. 1003.1-200x requires that error messages about problem tags
16056 files be displayed only if the requested tag is not found, and then, only once for each time that
16057 the **tag** edit option is changed.

16058 The requirement that the current edit buffer be unmodified is only necessary if the file indicated
16059 by the tag entry is not the same as the current file (as defined by the current path name).
16060 Historically, the file would be reloaded if the file name had changed, as well as if the file name
16061 was different from the current path name. For consistency and simplicity of specification,
16062 IEEE Std. 1003.1-200x does not permit this behavior, requiring that the name be the only factor in
16063 the decision.

16064 Historically, *vi* only searched for tags in the current file from the current cursor to the end of the
16065 file, and therefore, if the **wrapscan** option was not set, tags occurring before the current cursor
16066 were not found. IEEE Std. 1003.1-200x considers this a bug, and implementations are required to
16067 search for the first occurrence in the file, regardless.

16068 **Undo**

16069 The **undo** description deliberately uses the word ‘‘modified’’. The **undo** command is not
16070 intended to undo commands that replace the contents of the edit buffer, such as **edit**, **next**, **tag**,
16071 or **recover**.

16072 Cursor positioning after the **undo** command was inconsistent in the historical *vi*, sometimes
16073 attempting to restore the original cursor position (**global**, **undo**, and **v** commands), and
16074 sometimes, in the presence of maps, placing the cursor on the last line added or changed instead
16075 of the first. IEEE Std. 1003.1-200x requires a simplified behavior for consistency and simplicity of
16076 specification.

16077 **Version**

16078 The **version** command cannot be exactly specified since there is no widely-accepted definition of
16079 what the version information should contain. Implementations are encouraged to do something
16080 reasonably intelligent.

Write

Historically, the *ex* and *vi* message after a successful **read** or **write** command specified ''characters'', not ''bytes''. IEEE Std. 1003.1-200x requires that the number of bytes be displayed, not the number of characters because it may be difficult in multi-byte implementations to determine the number of characters written. Implementations are encouraged to clarify the message displayed to the user.

Implementation-defined tests are permitted so that implementations can make additional checks; for example, for locks or file modification times.

Historically, attempting to append to a nonexistent file caused an error. It has been left unspecified in IEEE Std. 1003.1-200x to permit implementations to let the **write** succeed, so that the append semantics are similar to those of the historical *csh*.

Historical *vi* permitted empty edit buffers to be written. However, since the way *vi* got around dealing with ''empty'' files was to always have a line in the edit buffer, no matter what, it wrote them as files of a single, empty line. IEEE Std. 1003.1-200x does not permit this behavior.

Historically, *ex* restored standard output and standard error to their values as of when *ex* was invoked, before writes to programs were performed. This could disturb the terminal configuration as well as be a security issue for some terminals. IEEE Std. 1003.1-200x does not permit this, requiring that the program output be captured and displayed as if by the *ex* **print** command.

Adjust Window

Historically, the line count was set to the value of the **scroll** option if the type character was end-of-file. This feature was broken on most historical implementations long ago, however, and is not documented anywhere. For this reason, IEEE Std. 1003.1-200x is resolutely silent.

Historically, the **z** command was <blank> character-sensitive and **z +** and **z** – did different things than **z+** and **z**– because the type could not be distinguished from a flag. (The commands **z .** and **z =** were historically invalid.) IEEE Std. 1003.1-200x requires conformance to this historical practice.

Historically, the **z** command was further <blank> character-sensitive in that the *count* could not be <blank> character-delimited; for example, the commands **z= 5** and **z– 5** were also invalid. Because the *count* is not ambiguous with respect to either the type character or the flags, this is not permitted by IEEE Std. 1003.1-200x.

Escape

Historically, *ex* filter commands only read the standard output of the commands, letting standard error appear on the terminal as usual. The *vi* utility, however, read both standard output and standard error. IEEE Std. 1003.1-200x requires the latter behavior for both *ex* and *vi*, for consistency.

Shift Left and Shift Right

Historically, it was possible to add shift characters to increase the effect of the command; for example, **<<<** outdented (or **>>>** indented) the lines 3 levels of indentation instead of the default 1. IEEE Std. 1003.1-200x requires conformance to historical practice.

16121 **<control>-D**

16122 Historically, the <control>-D command erased the prompt, providing the user with an unbroken
16123 presentation of lines from the edit buffer. This is not required by IEEE Std. 1003.1-200x;
16124 implementations are encouraged to provide it if possible. Historically, the <control>-D
16125 command took, and then ignored, a *count*. IEEE Std. 1003.1-200x does not permit this behavior.

16126 **Write Line Number**

16127 Historically, the *ex* **=** command, when executed in *ex* mode in an empty edit buffer, reported 0,
16128 and from open or visual mode, reported 1. For consistency and simplicity of specification,
16129 IEEE Std. 1003.1-200x does not permit this behavior.

16130 **Execute**

16131 Historically, *ex* did not correctly handle the inclusion of text input commands (that is, **append**,
16132 **insert**, and **change**) in executed buffers. IEEE Std. 1003.1-200x does not permit this exclusion for
16133 consistency.

16134 Historically, the logical contents of the buffer being executed did not change if the buffer itself
16135 were modified by the commands being executed; that is, buffer execution did not support self-
16136 modifying code. IEEE Std. 1003.1-200x requires conformance to historical practice.

16137 Historically, the **@** command took a range of lines, and the **@** buffer was executed once per line,
16138 with the current line (`'.'`) set to each specified line. IEEE Std. 1003.1-200x requires conformance
16139 to historical practice.

16140 Some historical implementations did not notice if errors occurred during buffer execution. This,
16141 coupled with the ability to specify a range of lines for the *ex* **@** command, makes it trivial to
16142 cause them to drop core. IEEE Std. 1003.1-200x requires that implementations stop buffer
16143 execution if any error occurs, if the specified line doesn't exist, or if the contents of the edit buffer
16144 itself are replaced (for example, the buffer executes the *ex* **:edit** command).

16145 **Regular Expressions in ex**

16146 Historical practice is that the characters in the replacement part of the last **s** command—that is,
16147 those matched by entering a `'~'` in the regular expression—were not further expanded by the
16148 regular expression engine. So, if the characters contained the string `"a.,"` they would match
16149 `'a'` followed by `"."` and not `'a'` followed by any character. IEEE Std. 1003.1-200x requires
16150 con formance to historical practice.

16151 **Edit Options in ex**

16152 The following paragraphs describe the historical behavior of some edit options that were not, for
16153 whatever reason, included in IEEE Std. 1003.1-200x. Implementations are strongly encouraged
16154 to only use these names if the functionality described here is fully supported.

16155 **extended** The **extended** edit option has been used in some implementations of *vi* to provide
16156 extended regular expressions instead of basic regular expressions This option was
16157 omitted from IEEE Std. 1003.1-200x because it is not widespread historical practice.

16158 **flash** The **flash** edit option historically caused the screen to flash instead of beeping on
16159 error. This option was omitted from IEEE Std. 1003.1-200x because it is not found
16160 in some historical implementations.

16161 **hardtabs** The **hardtabs** edit option historically defined the number of columns between
16162 hardware tab settings. This option was omitted from IEEE Std. 1003.1-200x
16163 because it was believed to no longer be generally useful.

modeline The **modeline** (sometimes named **modelines**) edit option historically caused *ex* or *vi* to read the five first and last lines of the file for editor commands. This option is a security problem, and vendors are strongly encouraged to delete it from historical implementations.

open The **open** edit option historically disallowed the *ex* **open** and **visual** commands. This edit option was omitted because these commands are required by IEEE Std. 1003.1-200x.

optimize The **optimize** edit option historically expedited text throughput by setting the terminal to not do automatic carriage returns when printing more than one logical line of output. This option was omitted from IEEE Std. 1003.1-200x because it was intended for terminals without addressable cursors, which are rarely, if ever, still used.

ruler The **ruler** edit option has been used in some implementations of *vi* to present a current row/column ruler for the user. This option was omitted from IEEE Std. 1003.1-200x because it is not widespread historical practice.

sourceany The **sourceany** edit option historically caused *ex* or *vi* to source start-up files that were owned by users other than the user running the editor. This option is a security problem, and vendors are strongly encouraged to remove it from their implementations.

timeout The **timeout** edit option historically enabled the (now standard) feature of only waiting for a short period before returning keys that could be part of a macro. This feature was omitted from IEEE Std. 1003.1-200x because its behavior is now standard, it is not widely useful, and it was rarely documented.

verbose The **verbose** edit option has been used in some implementations of *vi* to cause *vi* to output error messages for common errors; for example, attempting to move the cursor past the beginning or end of the line instead of only alerting the screen. (The historical *vi* only alerted the terminal and presented no message for such errors. The historical editor option **terse** did not select when to present error messages, it only made existing error messages more or less verbose.) This option was omitted from IEEE Std. 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they wish to provide error messages for naive users.

wraplen The **wraplen** edit option has been used in some implementations of *vi* to specify an automatic margin measured from the left margin instead of from the right margin. This is useful when multiple screen sizes are being used to edit a single file. This option was omitted from IEEE Std. 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they add this functionality.

autoindent, ai

Historically, the command **0a** did not do any autoindentation, regardless of the current indentation of line 1. IEEE Std. 1003.1-200x requires that any indentation present in line 1 be used.

autoprint, ap

Historically, the **autoprint** edit option was not completely consistent or based solely on modifications to the edit buffer. Exceptions were the **read** command (when reading from a file, but not from a filter), the **append**, **change**, **insert**, **global**, and **v** commands, all of which were not affected by **autoprint**, and the **tag** command, which was affected by **autoprint**. IEEE Std. 1003.1-200x requires conformance to historical practice.

Historically, the **autoprint** option only applied to the last of multiple commands entered using vertical-bar delimiters; for example, **delete** <newline> was affected by **autoprint**, but **delete|version** <newline> was not. IEEE Std. 1003.1-200x requires conformance to historical practice.

autowrite, aw

Appending the '!' character to the *ex* **next** command to avoid performing an automatic write was not supported in historical implementations. IEEE Std. 1003.1-200x requires that the behavior match the other *ex* commands for consistency.

ignorecase, ic

Historical implementations of case-insensitive matching (the **ignorecase** edit option) lead to counterintuitive situations when uppercase characters were used in range expressions. Historically, the process was as follows:

1. Take a line of text from the edit buffer.
2. Convert uppercase to lowercase in text line.
3. Convert uppercase to lowercase in regular expressions, except in character class specifications.
4. Match regular expressions against text.

This would mean that, with **ignorecase** in effect, the text:

```
The cat sat on the mat
```

would be matched by

```
/^the/
```

but not by:

```
/^[A–Z]he/
```

For consistency with other commands implementing regular expressions, IEEE Std. 1003.1-200x does not permit this behavior.

paragraphs, para

Earlier versions of IEEE Std. 1003.1-200x made the default **paragraphs** and **sections** edit options implementation-defined, arguing they were historically oriented to the UNIX system *troff* text formatter, and a ''portable user'' could use the **{**, **}**, **[[**, **]]**, **(**, and **)** commands in open or visual mode and have the cursor stop in unexpected places. IEEE Std. 1003.1-200x specifies their values in the POSIX locale because the unusual grouping (they only work when grouped into two characters at a time) means that they cannot be used for general purpose movement, regardless.

readonly

Implementations are encouraged to provide the best possible information to the user as to the read-only status of the file, with the exception that they should not consider the current special privileges of the process. This provides users a safety net because they must force the overwrite of read-only files, even when running with additional privileges.

The **readonly** edit option specification largely conforms to historical practice. The only difference is that historical implementations did not notice that the user had set the **readonly** edit option in cases where the file was already marked read-only for some reason, and would therefore reinitialize the **readonly** edit option the next time the contents of the edit buffer were replaced. This behavior is disallowed by IEEE Std. 1003.1-200x.

report

The requirement that lines copied to a buffer interact differently than deleted lines is historical practice. For example, if the **report** edit option is set to 3, deleting 3 lines will cause a report to be written, but 4 lines must be copied before a report is written.

The requirement that the *ex* **global**, **v**, **open**, **undo**, and **visual** commands present reports based on the total number of lines added or deleted during the command execution, and that commands executed by the **global** and **v** commands not present reports, is historical practice. IEEE Std. 1003.1-200x extends historical practice by requiring that buffer execution be treated similarly. The reasons for this are two-fold. Historically, only the report by the last command executed from the buffer would be seen by the user, as each new report would overwrite the last. In addition, the standard developers believed that buffer execution had more in common with **global** and **v** commands than it did with other *ex* commands, and should behave similarly, for consistency and simplicity of specification.

showmatch, sm

The length of time the cursor spends on the matching character is unspecified because the timing capabilities of systems are often inexact and variable. The time should be long enough for the user to notice, but not long enough for the user to become annoyed. Some implementations of *vi* have added a **matchtime** option that permits users to set the number of 0,1 second intervals the cursor pauses on the matching character.

showmode

The **showmode** option has been used in some historical implementations of *ex* and *vi* to display the current editing mode when in open or visual mode. The editing modes have generally included ‘‘command’’ and ‘‘input’’, and sometimes other modes such as ‘‘replace’’ and ‘‘change’’. The string was usually displayed on the bottom line of the screen at the far right-hand corner. In addition, a preceding ’*’ character often denoted if the contents of the edit buffer had been modified. The latter display has sometimes been part of the **showmode** option, and sometimes based on another option. This option was not available in the 4 BSD historical implementation of *vi*, but was viewed as generally useful, particularly to novice users, and is required by IEEE Std. 1003.1-200x.

The **smd** shorthand for the **showmode** option was not present in all historical implementations of the editor. IEEE Std. 1003.1-200x requires it, for consistency.

Not all historical implementations of the editor displayed a mode string for command mode, differentiating command mode from text input mode by the absence of a mode string. IEEE Std. 1003.1-200x permits this behavior for consistency with historical practice, but implementations are encouraged to provide a display string for both modes.

16289 **slowopen**

16290 Historically the **slowopen** option was automatically set if the terminal baud rate was less than
16291 1 200 baud, or if the baud rate was 1 200 baud and the **redraw** option was not set. The **slowopen**
16292 option had two effects. First, when inserting characters in the middle of a line, characters after
16293 the cursor would not be pushed ahead, but would appear to be overwritten. Second, when
16294 creating a new line of text, lines after the current line would not be scrolled down, but would
16295 appear to be overwritten. In both cases, ending text input mode would cause the screen to be
16296 refreshed to match the actual contents of the edit buffer. Finally, terminals that were sufficiently
16297 intelligent caused the editor to ignore the **slowopen** option. IEEE Std. 1003.1-200x permits most
16298 historical behavior, extending historical practice to require **slowopen** behaviors if the edit option
16299 is set by the user.

16300 **tags**

16301 The default path for tags files is left unspecified as implementations may have their own **tags**
16302 implementations that do not correspond to the historical ones. The default **tags** option value
16303 should probably at least include the file **./tags**.

16304 **term**

16305 Historical implementations of *ex* and *vi* ignored changes to the **term** edit option after the initial
16306 terminal information was loaded. This is permitted by IEEE Std. 1003.1-200x; however,
16307 implementations are encouraged to permit the user to modify their terminal type at any time.

16308 **terse**

16309 Historically, the **terse** edit option optionally provided a shorter, less descriptive error message,
16310 for some error messages. This is permitted, but not required, by IEEE Std. 1003.1-200x.
16311 Historically, most common visual mode errors (for example, trying to move the cursor past the
16312 end of a line) did not result in an error message, but simply alerted the terminal.
16313 Implementations wishing to provide messages for novice users are urged to do so based on the
16314 **edit** option **verbose**, and not **terse**.

16315 **window**

16316 In historical implementations, the default for the **window** edit option was based on the baud
16317 rate as follows:

16318 1. If the baud rate was less than 1 200, the **edit** option **w300** set the window value; for
16319 example, the line:

16320 `set w300=12`

16321 would set the window option to 12 if the baud rate was less than 1 200.

16322 2. If the baud rate was equal to 1 200, the **edit** option **w1200** set the window value.

16323 3. If the baud rate was greater than 1 200, the **edit** option **w9600** set the window value.

16324 The **w300**, **w1200**, and **w9600** options do not appear in IEEE Std. 1003.1-200x because of their
16325 dependence on specific baud rates.

16326 In historical implementations, the size of the window displayed by various commands was
16327 related to, but not necessarily the same as, the **window** edit option. For example, the size of the
16328 window was set by the *ex* command **visual 10**, but it did not change the value of the **window**
16329 edit option. However, changing the value of the **window** edit option did change the number of
16330 lines that were displayed when the screen was repainted. IEEE Std. 1003.1-200x does not permit

this behavior in the interests of consistency and simplicity of specification, and requires that all commands that change the number of lines that are displayed do it by setting the value of the **window** edit option.

wrapmargin, wm

Historically, the **wrapmargin** option did not affect maps inserting characters that also had associated *count*s; for example **:map K 5aABC DEF**. Unfortunately, there are widely used maps that depend on this behavior. For consistency and simplicity of specification, IEEE Std. 1003.1-200x does not permit this behavior.

Historically, **wrapmargin** was calculated using the column display width of all characters on the screen. For example, an implementation using `"^I"` to represent <tab> characters when the **list** edit option was set, where `'^'` and `'I'` each took up a single column on the screen, would calculate the **wrapmargin** based on a value of 2 for each <tab> character. The **number** edit option similarly changed the effective length of the line as well. IEEE Std. 1003.1-200x requires conformance to historical practice.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed, removing the **+***command* and – options.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–l** option is added.
- In the *map* command description, the sequence **#***digit* is added.
- The **directory**, **edcompatible**, **redraw**, **slowopen**, and **lisp** edit options are added.

The *ex* utility is extensively changed for alignment with the IEEE P1003.2b draft standard. This includes changes as a result of the IEEE PASC Interpretations 1003.2 #31, #38, #49, #50, #51, #52, #55, #56, #57, #61, #62, #63, #64, #65, and #78.

16366 **NAME**

16367 expand — convert tabs to spaces

16368 **SYNOPSIS**

16369 UP `expand [–t tablist][file ...]`

16370

16371 **DESCRIPTION**

16372 The *expand* utility shall write files or the standard input to the standard output with <tab>
16373 characters replaced with one or more <space> characters needed to pad to the next tab stop. Any
16374 <backspace> characters shall be copied to the output and cause the column position count for
16375 tab stop calculations to be decremented; the column position count shall not be decremented
16376 below zero.

16377 **OPTIONS**

16378 The *expand* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
16379 12.2, Utility Syntax Guidelines.

16380 The following option shall be supported:

16381 **–t** *tablist* Specify the tab stops. The application shall ensure that the argument *tablist*
16382 consists of either a single positive decimal integer or a list of tabstops. If a single
16383 number is given, tabs shall be set that number of column positions apart instead of
16384 the default 8.

16385 If a list of tabstops is given, the application shall ensure that it consists of a list of
16386 two or more positive decimal integers, separated by <blank> characters or comms,
16387 in ascending order. The tabs shall be set at those specific column positions. Each
16388 tab stop *N* shall be an integer value greater than zero, and the list is in strictly
16389 ascending order. This is taken to mean that, from the start of a line of output,
16390 tabbing to position *N* shall cause the next character output to be in the (*N*+1)th
16391 column position on that line.

16392 In the event of *expand* having to process a <tab> character at a position beyond the
16393 last of those specified in a multiple tab-stop list, the <tab> character shall be
16394 replaced by a single <space> character in the output.

16395 **OPERANDS**

16396 The following operand shall be supported:

16397 *file* The path name of a text file to be used as input.

16398 **STDIN**

16399 See the INPUT FILES section.

16400 **INPUT FILES**

16401 Input files shall be text files.

16402 **ENVIRONMENT VARIABLES**

16403 The following environment variables shall affect the execution of *expand*:

16404 *LANG* Provide a default value for the internationalization variables that are unset or null.
16405 If *LANG* is unset or null, the corresponding value from the implementation-
16406 defined default locale shall be used. If any of the internationalization variables
16407 contains an invalid setting, the utility shall behave as if none of the variables had
16408 been defined.

16409 *LC_ALL* If set to a non-empty string value, override the values of all the other
16410 internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab> and <space> characters, and for the determination of the width in column positions each character would occupy on an output device.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be equivalent to the input files with <tab> characters converted into the appropriate number of <space> characters.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion

>0 An error occurred.

CONSEQUENCES OF ERRORS

The *expand* utility shall terminate with an error message and non-zero exit status upon encountering difficulties accessing one of the *file* operands.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *expand* utility is useful for preprocessing text files (before sorting, looking at specific columns, and so on) that contain <tab>s.

See the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.106, Column Position.

The *tablist* option-argument consists of integers in ascending order. Utility Syntax Guideline 8 mandates that *expand* shall accept the integers (within the single argument) separated using either commas or <blank>s.

FUTURE DIRECTIONS

None.

16451 **SEE ALSO**

16452 *tabs*, *unexpand*

16453 **CHANGE HISTORY**

16454 First released in Issue 4.

16455 **Issue 6**

16456 This utility is now marked as part of the User Portability Utilities option.

16457 The APPLICATION USAGE section is added.

16458 The obsolescent SYNOPSIS is removed.

16459 The *LC_CTYPE* environment variable description is updated to align with the IEEE P1003.2b
16460 draft standard.

16461 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

16462 **NAME**

16463 expr — evaluate arguments as an expression

16464 **SYNOPSIS**

16465 `expr` *operand*

16466 **DESCRIPTION**

16467 The *expr* utility shall evaluate an expression and write the result to standard output.

16468 **OPTIONS**

16469 None.

16470 **OPERANDS**

16471 The single expression evaluated by *expr* shall be formed from the operands, as described in the
16472 EXTENDED DESCRIPTION section. The application shall ensure that each of the expression
16473 operator symbols:

16474 `( ) | & = > >= < <= != + – * / % :`

16475 and the symbols *integer* and *string* in the table are provided as separate arguments to *expr*.

16476 **STDIN**

16477 Not used.

16478 **INPUT FILES**

16479 None.

16480 **ENVIRONMENT VARIABLES**

16481 The following environment variables shall affect the execution of *expr*:

16482 *LANG* Provide a default value for the internationalization variables that are unset or null.
16483 If *LANG* is unset or null, the corresponding value from the implementation-
16484 defined default locale shall be used. If any of the internationalization variables
16485 contains an invalid setting, the utility shall behave as if none of the variables had
16486 been defined.

16487 *LC_ALL* If set to a non-empty string value, override the values of all the other
16488 internationalization variables.

16489 *LC_COLLATE*

16490 Determine the locale for the behavior of ranges, equivalence classes, and multi-
16491 character collating elements within regular expressions and by the string
16492 comparison operators.

16493 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
16494 characters (for example, single-byte as opposed to multi-byte characters in
16495 arguments) and the behavior of character classes within regular expressions.

16496 *LC_MESSAGES*

16497 Determine the locale that should be used to affect the format and contents of
16498 diagnostic messages written to standard error.

16499 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

16500 **ASYNCHRONOUS EVENTS**

16501 Default.

16502 **STDOUT**

16503 The *expr* utility shall evaluate the expression and write the result, followed by a <newline>
16504 character, to standard output.

16505 **STDERR**

16506 Used only for diagnostic messages.

16507 **OUTPUT FILES**

16508 None.

16509 **EXTENDED DESCRIPTION**

16510 The formation of the expression to be evaluated is shown in the following table. The symbols
16511 *expr*, *expr1*, and *expr2* represent expressions formed from *integer* and *string* symbols and the
16512 expression operator symbols (all separate arguments) by recursive application of the constructs
16513 described in the table. The expressions are listed in order of increasing precedence, with equal-
16514 precedence operators grouped between horizontal lines. All of the operators shall be left-
16515 associative.

16516

Expression	Description
expr1 | *expr2*	Returns the evaluation of *expr1* if it is neither null nor zero; otherwise, returns the evaluation of *expr2* if it is not null; otherwise, zero.
expr1 & *expr2*	Returns the evaluation of *expr1* if neither expression evaluates to null or zero; otherwise, returns zero.
	Returns the result of a decimal integer comparison if both arguments are integers; otherwise, returns the result of a string comparison using the locale-specific collation sequence. The result of each comparison is 1 if the specified relationship is true, or 0 if the relationship is false.
expr1 = *expr2*	Equal.
expr1 > *expr2*	Greater than.
expr1 >= *expr2*	Greater than or equal.
expr1 < *expr2*	Less than.
expr1 <= *expr2*	Less than or equal.
expr1 != *expr2*	Not equal.
expr1 + *expr2*	Addition of decimal integer-valued arguments.
expr1 – *expr2*	Subtraction of decimal integer-valued arguments.
expr1 * *expr2*	Multiplication of decimal integer-valued arguments.
expr1 / *expr2*	Integer division of decimal integer-valued arguments, producing an integer result.
expr1 % *expr2*	Remainder of integer division of decimal integer-valued arguments.
expr1 : *expr2*	Matching expression; see below.
(*expr*)	Grouping symbols. Any expression can be placed within parentheses. Parentheses can be nested to a depth of {EXPR_NEST_MAX}.
integer	An argument consisting only of an (optional) unary minus followed by digits.
string	A string argument; see below.

16547 **Matching Expression**

16548 The `':'` matching operator shall compare the string resulting from the evaluation of *expr1* with
16549 the regular expression pattern resulting from the evaluation of *expr2*. Regular expression syntax
16550 shall be that defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic
16551 Regular Expressions, except that all patterns are anchored to the beginning of the string (that is,
16552 only sequences starting at the first character of a string are matched by the regular expression)
16553 and, therefore, it is unspecified whether `'^'` is a special character in that context. Usually, the
16554 matching operator shall return a string representing the number of characters matched (`'0'` on
16555 failure). Alternatively, if the pattern contains at least one regular expression subexpression
16556 `"[\(...\)]"`, the string corresponding to `"\1"` shall be returned.

16557 **String Operand**

16558 A string argument is an argument that cannot be identified as an *integer* argument or as one of
16559 the expression operator symbols shown in the OPERANDS section.

16560 The use of string arguments **length**, **substr**, **index**, or **match** produces unspecified results.

16561 **EXIT STATUS**

16562 The following exit values shall be returned:

16563 0 The *expression* evaluates to neither null nor zero.

16564 1 The *expression* evaluates to null or zero.

16565 2 Invalid *expression*.

16566 >2 An error occurred.

16567 **CONSEQUENCES OF ERRORS**

16568 Default.

16569 **APPLICATION USAGE**

16570 After argument processing by the shell, *expr* is not required to be able to tell the difference
16571 between an operator and an operand except by the value. If `"$a"` is `'='`, the command:

16572 ```
expr $a = '='
```

16573 looks like:

16574 ```
expr = = =
```

16575 as the arguments are passed to *expr* (and they all may be taken as the `'='` operator). The
16576 following works reliably:

16577 ```
expr X$a = X=
```

16578 Also note that this volume of IEEE Std. 1003.1-200x permits implementations to extend utilities.
16579 The *expr* utility permits the integer arguments to be preceded with a unary minus. This means
16580 that an integer argument could look like an option. Therefore, the portable application must
16581 employ the `"--"` construct of Guideline 10 of the Base Definitions volume of
16582 IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines to protect its operands if there is
16583 any chance the first operand might be a negative integer (or any string with a leading minus).

16584 **EXAMPLES**

16585 The *expr* utility has a rather difficult syntax:

16586 • Many of the operators are also shell control operators or reserved words, so they have to be
16587 escaped on the command line.
```

- Each part of the expression is composed of separate arguments, so liberal usage of <blank> characters is required. For example:

Invalid	Valid
`expr 1+2`	`expr 1 + 2`
`expr "1 + 2"`	`expr 1 + 2`
`expr 1 + (2 * 3)`	`expr 1 + \( 2 \* 3 \)`

In many cases, the arithmetic and string features provided as part of the shell command language are easier to use than their equivalents in *expr*. Newly written scripts should avoid *expr* in favor of the new features within the shell; see Section 2.5 (on page 2241) and Section 2.6.4 (on page 2248).

The following command:

```
a=$(expr $a + 1)
```

adds 1 to the variable *a*.

The following command, for `"$a"` equal to either **/usr/abc/file** or just **file**:

```
expr $a : '.*/\(.*\)' \| $a
```

returns the last segment of a path name (that is, **file**). Applications should avoid the character `'/'` used alone as an argument: *expr* may interpret it as the division operator.

The following command:

```
expr "//$a" : '.*/\(.*\)'
```

is a better representation of the previous example. The addition of the `"//"` characters eliminates any ambiguity about the division operator and simplifies the whole expression. Also note that path names may contain characters contained in the *IFS* variable and should be quoted to avoid having `"$a"` expand into multiple arguments.

The following command:

```
expr "$VAR" : '.*'
```

returns the number of characters in *VAR*.

RATIONALE

In an early proposal, EREs were used in the matching expression syntax. This was changed to BREs to avoid breaking historical applications.

The use of a leading circumflex in the BRE is unspecified because many historical implementations have treated it as a special character, despite their system documentation. For example:

```
expr foo : ^foo     expr ^foo : ^foo
```

return 3 and 0, respectively, on those systems; their documentation would imply the reverse. Thus, the anchoring condition is left unspecified to avoid breaking historical scripts relying on this undocumented feature.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

fc — process the command history list

SYNOPSIS

UP

```
fc [–r][–e editor] [first[last]]
fc –l[–nr] [first[last]]
fc –s[old=new][first]
```

DESCRIPTION

The *fc* utility shall list, or shall edit and re-execute, commands previously entered to an interactive *sh*.

The command history list shall reference commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command shall not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches an implementation-defined upper limit, which shall be no smaller than the value in *HISTSIZE* or 32 767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, *fc* shall maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.

When commands are edited (when the **–l** option is not specified), the resulting lines shall be entered at the end of the history list and then re-executed by *sh*. The *fc* command that caused the editing shall not be entered into the history list. If the editor returns a non-zero exit status, this shall suppress the entry into the history list and the command re-execution. Any command line variable assignments or redirection operators used with *fc* shall affect both the *fc* command itself as well as the command that results; for example:

```
fc –s –– –1 2>/dev/null
```

reinvokes the previous command, suppressing standard error for both *fc* and the previous command.

OPTIONS

The *fc* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–e *editor* Use the editor named by *editor* to edit the commands. The *editor* string is a utility name, subject to search via the *PATH* variable (see the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables). The value in the *FCEDIT* variable shall be used as a default when **–e** is not specified. If *FCEDIT* is null or unset, *ed* shall be used as the editor.

–l (The letter ell.) List the commands rather than invoking an editor on them. The commands shall be written in the sequence indicated by the *first* and *last* operands, as affected by **–r**, with each command preceded by the command number.

–n Suppress command numbers when listing with **–l**.

–r Reverse the order of the commands listed (with **–l**) or edited (with neither **–l** nor **–s**).

16728 **–s** Reexecute the command without invoking an editor.

16729 **OPERANDS**

16730 The following operands shall be supported:

16731 *first*, *last*

16732 Select the commands to list or edit. The number of previous commands that can be
16733 accessed shall be determined by the value of the *HISTSIZE* variable. The value of
16734 *first* or *last* or both shall be one of the following:

16735 **[+]***number* A positive number representing a command number; command
16736 numbers can be displayed with the **–l** option.

16737 *–number* A negative decimal number representing the command that was
16738 executed *number* of commands previously. For example, –1 is the
16739 immediately previous command.

16740 *string* A string indicating the most recently entered command that begins
16741 with that string. If the *old=new* operand is not also specified with **–s**,
16742 the string form of the *first* operand cannot contain an embedded
16743 equal sign.

16744 When the synopsis form with **–s** is used:

16745 • If *first* is omitted, the previous command shall be used.

16746 For the synopsis forms without **–s**:

16747 • If *last* is omitted, *last* shall default to the previous command when **–l** is
16748 specified; otherwise, it shall default to *first*.

16749 • If *first* and *last* are both omitted, the previous 16 commands shall be listed or
16750 the previous single command shall be edited (based on the **–l** option).

16751 • If *first* and *last* are both present, all of the commands from *first* to *last* shall be
16752 edited (without **–l**) or listed (with **–l**). Editing multiple commands shall be
16753 accomplished by presenting to the editor all of the commands at one time, each
16754 command starting on a new line. If *first* represents a newer command than *last*,
16755 the commands shall be listed or edited in reverse sequence, equivalent to using
16756 **–r**. For example, the following commands on the first line are equivalent to the
16757 corresponding commands on the second:

16758 `fc –r 10 20` `fc 30 40`
16759 `fc 20 10` `fc –r 40 30`

16760 • When a range of commands is used, it shall not be an error to specify *first* or *last*
16761 values that are not in the history list; *fc* shall substitute the value representing
16762 the oldest or newest command in the list, as appropriate. For example, if there
16763 are only ten commands in the history list, numbered 1 to 10:

16764 `fc –l`
16765 `fc 1 99`

16766 shall list and edit, respectively, all ten commands.

16767 *old=new* Replace the first occurrence of string *old* in the commands to be re-executed by the
16768 string *new*.

16769 **STDIN**

16770 Not used.

16771 **INPUT FILES**

16772 None.

16773 **ENVIRONMENT VARIABLES**

16774 The following environment variables shall affect the execution of *fc*:

16775 *FCEDIT* This variable, when expanded by the shell, shall determine the default value for
16776 the **–e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be
16777 used as the editor.

16778 *HISTFILE* Determine a path name naming a command history file. If the *HISTFILE* variable is
16779 not set, the shell may attempt to access or create a file **.sh_history** in the directory
16780 referred to by the *HOME* environment variable. If the shell cannot obtain both read |
16781 and write access to, or create, the history file, it shall use an unspecified |
16782 mechanism that allows the history to operate properly. (References to history |
16783 ''file'' in this section shall be understood to mean this unspecified mechanism in |
16784 such cases.) An implementation may choose to access this variable only when |
16785 initializing the history file; this initialization shall occur when *fc* or *sh* first attempt |
16786 to retrieve entries from, or add entries to, the file, as the result of commands issued
16787 by the user, the file named by the *ENV* variable, or implementation-defined system |
16788 start-up files. In some historical shells, the history file is initialized just after the |
16789 *ENV* file has been processed. Therefore, it is implementation-defined whether |
16790 changes made to *HISTFILE* after the history file has been initialized are effective.
16791 Implementations may choose to disable the history list mechanism for users with
16792 appropriate privileges who do not set *HISTFILE*; the specific circumstances under
16793 which this occurs are implementation-defined. If more than one instance of the |
16794 shell is using the same history file, it is unspecified how updates to the history file |
16795 from those shells interact. As entries are deleted from the history file, they shall be
16796 deleted oldest first. It is unspecified when history file entries are physically
16797 removed from the history file.

16798 *HISTSIZE* Determine a decimal number representing the limit to the number of previous
16799 commands that are accessible. If this variable is unset, an unspecified default
16800 greater than or equal to 128 shall be used. The maximum number of commands in
16801 the history list is unspecified, but shall be at least 128. An implementation may
16802 choose to access this variable only when initializing the history file, as described
16803 under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE*
16804 after the history file has been initialized are effective.

16805 *LANG* Provide a default value for the internationalization variables that are unset or null.
16806 If *LANG* is unset or null, the corresponding value from the implementation- |
16807 defined default locale shall be used. If any of the internationalization variables |
16808 contains an invalid setting, the utility shall behave as if none of the variables had
16809 been defined.

16810 *LC_ALL* If set to a non-empty string value, override the values of all the other
16811 internationalization variables.

16812 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
16813 characters (for example, single-byte as opposed to multi-byte characters in
16814 arguments and input files).

16815 *LC_MESSAGES*

16816 Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is used to list commands, the format of each command in the list shall be as follows:

`"%d\t%s\n", <line number>, <command>`

If both the **–l** and **–n** options are specified, the format of each command shall be:

`"\t%s\n", <command>`

If the <*command*> consists of more than one line, the lines after the first shall be displayed as:

`"\t%s\n", <continued-command>`

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion of the listing.

>0 An error occurred.

Otherwise, the exit status shall be that of the commands executed by *fc*.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Since editors sometimes use file descriptors as integral parts of their editing, redirecting their file descriptors as part of the *fc* command can produce unexpected results. For example, if *vi* is the *FCEDIT* editor, the command:

```
fc –s | more
```

does not work correctly on many systems.

Users on windowing systems may want to have separate history files for each window by setting *HISTFILE* as follows:

```
HISTFILE=$HOME/.sh_hist$$
```

EXAMPLES

None.

RATIONALE

This utility is based on the *fc* built-in of the KornShell.

An early proposal specified the **–e** option as **[–e** *editor* **[***old***=** *new* **]]**, which is not historical practice. Historical practice in *fc* of either **[–e** *editor***]** or **[–e – [** *old***=** *new* **]]** is acceptable, but not

both together. To clarify this, a new option –**s** was introduced replacing the **[**–**e** –**]**. This resolves the conflict and makes *fc* conform to the Utility Syntax Guidelines.

HISTFILE Some implementations of the KornShell check for the superuser and do not create a history file unless *HISTFILE* is set. This is done primarily to avoid creating unlinked files in the root file system when logging in during single-user mode. *HISTFILE* must be set for the superuser to have history.

HISTSIZE Needed to limit the size of history files. It is the intent of the standard developers that when two shells share the same history file, commands that are entered in one shell shall be accessible by the other shell. Because of the difficulties of synchronization over a network, the exact nature of the interaction is unspecified.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the settings the user has for *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user can influence its characteristics. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Because of these situations, the text requires the initialization process to be implementation-defined.

Consideration was given to omitting the *fc* utility in favor of the command line editing feature in *sh*. For example, in *vi* editing mode, typing `"<ESC> v"` is equivalent to:

```
EDITOR=vi fc
```

However, the *fc* utility allows the user the flexibility to edit multiple commands simultaneously (such as *fc* 10 20) and to use editors other than those supported by *sh* for command line editing.

In the KornShell, the alias **r** (''re-do'') is preset to *fc* –**e** – (equivalent to the POSIX *fc* –**s**). This is probably an easier command name to remember than *fc* (''fix command''), but it does not meet the Utility Syntax Guidelines. Renaming *fc* to *hist* or *redo* was considered, but since this description closely matches historical KornShell practice already, such a renaming was seen as gratuitous. Users are free to create aliases whenever odd historical names such as *fc*, *awk*, *cat*, *grep*, or *yacc* are standardized by POSIX.

Command numbers have no ordering effects; they are like serial numbers. The –**r** option and –*number* operand address the sequence of command execution, regardless of serial numbers. So, for example, if the command number wrapped back to 1 at some arbitrary point, there would be no ambiguity associated with traversing the wrap point. For example, if the command history were:

```
32766: echo 1
32767: echo 2
1: echo 3
```

the number –2 refers to command 32 767 because it is the second previous command, regardless of serial number.

FUTURE DIRECTIONS

16899 **CHANGE HISTORY**

16900 First released in Issue 4.

16901 **Issue 5**

16902 FUTURE DIRECTIONS section added.

16903 **Issue 6**

16904 This utility is now marked as part of the User Portability Utilities option.

16905 In the ENVIRONMENT VARIABLES section, the text ‘‘user’s home directory’’ is updated to
16906 ‘‘directory referred to by the *HOME* environment variable’’.

16907 **NAME**

16908 fg — run jobs in the foreground

16909 **SYNOPSIS**

16910 UP `fg [`*job_id*`]`

16911

16912 **DESCRIPTION**

16913 If job control is enabled (see the description of *set* –**m**), the *fg* utility shall move a background job
16914 from the current environment (see Section 2.13 (on page 2273)) into the foreground.

16915 Using *fg* to place a job into the foreground shall remove its process ID from the list of those
16916 ‘‘known in the current shell execution environment’’; see Section 2.9.3.1 (on page 2259).

16917 **OPTIONS**

16918 None.

16919 **OPERANDS**

16920 The following operand shall be supported:

16921 *job_id* Specify the job to be run as a foreground job. If no *job_id* operand is given, the
16922 *job_id* for the job that was most recently suspended, placed in the background or
16923 run as a background job, shall be used. The format of *job_id* is described in the Base |
16924 Definitions volume of IEEE Std. 1003.1-200x, Section 3.205, Job Control Job ID. |

16925 **STDIN**

16926 Not used.

16927 **INPUT FILES**

16928 None.

16929 **ENVIRONMENT VARIABLES**

16930 The following environment variables shall affect the execution of *fg*:

16931 *LANG* Provide a default value for the internationalization variables that are unset or null.
16932 If *LANG* is unset or null, the corresponding value from the implementation- |
16933 defined default locale shall be used. If any of the internationalization variables |
16934 contains an invalid setting, the utility shall behave as if none of the variables had
16935 been defined.

16936 *LC_ALL* If set to a non-empty string value, override the values of all the other
16937 internationalization variables.

16938 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
16939 characters (for example, single-byte as opposed to multi-byte characters in
16940 arguments).

16941 *LC_MESSAGES*

16942 Determine the locale that should be used to affect the format and contents of
16943 diagnostic messages written to standard error.

16944 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

16945 **ASYNCHRONOUS EVENTS**

16946 Default.

16947 **STDOUT**

16948 The *fg* utility shall write the command line of the job to standard output in the following format:

16949 `"%s\n", <`*command*`>`

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *fg* utility shall exit with an error and no job shall be placed in the foreground.

APPLICATION USAGE

The *fg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg* (on page 2422). For this reason, *fg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of IEEE Std. 1003.1-200x have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of IEEE Std. 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

FUTURE DIRECTIONS

None.

SEE ALSO

bg, *kill*, *jobs*, *wait*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The JC marking is removed from the SYNOPSIS since job control is mandatory is this issue.

16988 **NAME**

16989 file — determine file type

16990 **SYNOPSIS**

16991 UP
```
file [–dhi][–M file][–m file] file ...
```
16992

16993 **DESCRIPTION**

16994 The *file* utility shall perform a series of tests on each specified *file* in an attempt to classify it:

16995 1. If the file is not a regular file, its file type shall be identified. The file types directory, FIFO,
16996 block special, and character special shall be identified as such. Other implementation-
16997 defined file types may also be identified.

16998 2. If the file is a regular file, and:

16999 a. The file is zero-length, it shall be identified as an empty file.

17000 b. The file is not zero-length, *file* shall examine an initial segment of the file and shall
17001 make a guess at identifying its contents or whether it is an executable binary file.
17002 (The answer is not guaranteed to be correct.)

17003 If *file* does not exist, cannot be read, or its file status could not be determined, the output shall
17004 indicate that the file was processed, but that its type could not be determined.

17005 If *file* is a symbolic link, by default the link shall be resolved and *file* shall test the type of file
17006 referenced by the symbolic link.

17007 **OPTIONS**

17008 The *file* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
17009 12.2, Utility Syntax Guidelines.

17010 The following options shall be supported by the implementation:

17011 **–d** Apply any default system tests to the file.

17012 **–h** When a symbolic link is encountered, identify the file as a symbolic link. If **–h** is
17013 not specified and *file* is a symbolic link that refers to a nonexistent file, *file* shall
17014 identify the file as a symbolic link, as if **–h** had been specified.

17015 **–i** If a file is a regular file, do not attempt to classify the type of the file further, but
17016 identify the file as specified in the STDOUT section, using a <*type*> string that
17017 contains the string `"regular file"`.

17018 **–M** *file* Specify the name of a file containing tests that shall be applied to a file in order to
17019 classify it (see the EXTENDED DESCRIPTION). No default system tests shall be
17020 applied.

17021 **–m** *file* Specify the name of a file containing tests that shall be applied to a file in order to
17022 classify it (see the EXTENDED DESCRIPTION).

17023 If multiple instances of the **–m**, **–d**, or **–M** options are specified, the concatenation of the tests
17024 specified, in the order specified, shall be the set of tests that are applied. If a **–M** option is
17025 specified, no tests other than those specified using the **–d**, **–M**, and **–m** options shall be applied
17026 to the file. If neither the **–d** nor **–M** options are specified, any default system tests shall be
17027 applied after any tests specified using the **–m** option.

17028 **OPERANDS**

17029 The following operand shall be supported:

17030 *file* A path name of a file to be tested.

17031 **STDIN**

17032 Not used.

17033 **INPUT FILES**

17034 The *file* can be any file type.

17035 **ENVIRONMENT VARIABLES**

17036 The following environment variables shall affect the execution of *file*:

17037 *LANG* Provide a default value for the internationalization variables that are unset or null.
17038 If *LANG* is unset or null, the corresponding value from the implementation-
17039 defined default locale shall be used. If any of the internationalization variables
17040 contains an invalid setting, the utility shall behave as if none of the variables had
17041 been defined.

17042 *LC_ALL* If set to a non-empty string value, override the values of all the other
17043 internationalization variables.

17044 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
17045 characters (for example, single-byte as opposed to multi-byte characters in
17046 arguments and input files).

17047 *LC_MESSAGES*
17048 Determine the locale that should be used to affect the format and contents of
17049 diagnostic messages written to standard error and informative messages written to
17050 standard output.

17051 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

17052 **ASYNCHRONOUS EVENTS**

17053 Default.

17054 **STDOUT**

17055 In the POSIX locale, the following format shall be used to identify each operand, *file* specified:

17056 `"%s: %s\n", <file>, <type>`

17057 The values for <*type*> are unspecified, except that in the POSIX locale, if *file* is identified as one
17058 of the types listed in the following table, <*type*> shall contain (but is not limited to) the
17059 corresponding string. Each space shown in the strings shall be exactly one <space> character.

17060 **Table 4-8** File Utility Output Strings

17061 **If *file* is a:**	**<*type*> shall contain the string:**
17062 Directory	directory
17063 FIFO	fifo
17064 Block special	block special
17065 Character special	character special
17066 Executable binary	executable
17067 Empty regular file	empty
17068 Symbolic link	symbolic link to
17069 *ar* archive library (see *ar*)	archive
17070 Extended *cpio* format (see *pax*)	cpio archive
17071 Extended *tar* format (see **ustar** in *pax*)	tar archive
17072 Shell script	commands text
17073 C-language source	c program text
17074 FORTRAN source	fortran program text

17075 If *file* is identified as a symbolic link (see **–h**), the following alternative output format shall be
17076 used:

17077 `"%s: %s %s\n", <file>, <type>, <contents of link>"`

17078 If the file named by the *file* operand does not exist or cannot be read, the string `"cannot open"`
17079 shall be included as part of the <*type*> field, but this shall not be considered an error that affects
17080 the exit status. If the type of the file named by the *file* operand cannot be determined, the string
17081 `"data"` shall be included as part of the <*type*> field, but this shall not be considered an error that
17082 affects the exit status.

17083 **STDERR**

17084 Used only for diagnostic messages.

17085 **OUTPUT FILES**

17086 None.

17087 **EXTENDED DESCRIPTION**

17088 A file specified as an option-argument to the **–m** or **–M** options shall contain one test per line,
17089 which shall be applied to the file. If the test succeeds, the message field of the line shall be
17090 printed and no further tests shall be applied, with the exception that tests on immediately
17091 following lines beginning with a single `'>'` character shall be applied.

17092 Each line shall be composed of the following four <blank>-separated fields:

17093 *offset* An unsigned number (optionally preceded by a single `'>'` character) specifying
17094 the *offset*, in bytes, of the value in the file that is to be compared against the *value*
17095 field of the line. If the file is shorter than the specified offset, the test shall fail.

17096 If the *offset* begins with the character `'>'`, the test contained in the line shall not be
17097 applied to the file unless the test on the last line for which the *offset* did not begin
17098 with a `'>'` was successful. By default, the *offset* shall be interpreted as an unsigned
17099 decimal number. With a leading 0x or 0X, the *offset* shall be interpreted as a
17100 hexadecimal number; otherwise, with a leading 0, the *offset* shall be interpreted as
17101 an octal number.

17102 *type* The type of the value in the file to be tested. The type shall consist of the type
17103 specification characters **c**, **d**, **f**, **s**, and **u**, specifying character, signed decimal,
17104 floating point, string, and unsigned decimal, respectively.

17105 The *type* string shall be interpreted as the bytes from the file starting at the
17106 specified *offset* and including the same number of bytes specified by the *value* field.
17107 If insufficient bytes remain in the file past the *offset* to match the *value* field, the test
17108 shall fail.

17109 The type specification characters **d**, **f**, and **u** can be followed by an optional
17110 unsigned decimal integer that specifies the number of bytes represented by the
17111 type. The type specification character **f** can be followed by an optional **F**, **D**, or **L**,
17112 indicating that the value is of type **float**, **double**, or **long double**, respectively. The
17113 type specification characters **d** and **u** can be followed by an optional **C**, **S**, **I**, or **L**,
17114 indicating that the value is of type **char**, **short**, **int**, or **long**, respectively.

17115 The default number of bytes represented by the type specifiers **d**, **f**, and **u** shall
17116 correspond to their respective C-language types as follows. If the system claims
17117 conformance to the C-Language Development Utilities option, those specifiers
17118 shall correspond to the default sizes used in the *c99* utility. Otherwise, the default |
17119 sizes shall be implementation-defined. |

17120 For the type specifier characters **d** and **u**, the default number of bytes shall |
17121 correspond to the size of a basic integer type of the implementation. For these |
17122 specifier characters, the implementation shall support values of the optional |
17123 number of bytes to be converted corresponding to the number of bytes in the C-
17124 language types **char**, **short**, **int**, or **long**. These numbers can also be specified by an
17125 application as the characters **C**, **S**, **I**, and **L**, respectively. The byte order used when
17126 interpreting numeric values is implementation-defined, but shall correspond to the |
17127 order in which a constant of the corresponding type is stored in memory on the |
17128 system.

17129 For the type specifier **f**, the default number of bytes shall correspond to the number
17130 of bytes in the basic double precision floating-point data type of the underlying
17131 implementation. The implementation shall support values of the optional number
17132 of bytes to be converted corresponding to the number of bytes in the C-language
17133 types **float**, **double**, and **long double**. These numbers can also be specified by an
17134 application as the characters **F**, **D**, and **L**, respectively.

17135 All type specifiers, except for **s**, can be followed by a mask specifier of the form
17136 &*number*. The mask value shall be AND'ed with the value before the comparison
17137 with the value from the file is made. By default, the mask shall be interpreted as an
17138 unsigned decimal number. With a leading 0x or 0X, the mask shall be interpreted
17139 as an unsigned hexadecimal number; otherwise, with a leading 0, the mask shall be
17140 interpreted as an unsigned octal number.

17141 The strings **byte**, **short**, **long**, and **string** shall also be supported as type fields,
17142 being interpreted as **dC**, **dS**, **dL**, and **s**, respectively.

17143 *value* The *value* to be compared with the value from the file.

17144 Any value that contains a character that is not a digit, other than a leading sign
17145 (`'+'` or `'−'`) or a leading 0x or 0X, shall be interpreted as a string. The test shall
17146 succeed only when a string value exactly matches the bytes from the file.

17147 If the *value* is a string, it can contain the following sequences:

17148 `\`*character* The backslash-escape sequences as specified in the Base |
17149 Definitions volume of IEEE Std. 1003.1-200x, Table 5-1, Escape |
17150 Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, |
17151 `'\n'`, `'\r'`, `'\t'`, `'\v'`). The results of using any other

character, other than an octal digit, following the backslash are unspecified.

\octal Octal sequences that can be used to represent characters with specific coded values. An octal sequence shall consist of a backslash followed by the longest sequence of one, two, or three octal-digit characters (01234567). If the size of a byte on the system is greater than 9 bits, the valid escape sequence used to represent a byte is implementation-defined.

By default, any value that is not a string shall be interpreted as a signed decimal number. Any such value, with a leading 0x or 0X, shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading zero, the value shall be interpreted as an unsigned octal number.

If the value is not a string, it can be preceded by a character indicating the comparison to be performed. Permissible characters and the comparisons they specify are as follows:

= The test shall succeed if the value from the file equals the *value* field.

< The test shall succeed if the value from the file is less than the *value* field.

> The test shall succeed if the value from the file is greater than the *value* field.

& The test shall succeed if all of the bits in the *value* field are set in the value from the file.

^ The test shall succeed if at least one of the bits in the *value* field is not set in the value from the file.

x The test shall succeed if there is any value in the file.

message The *message* to be printed if the test succeeds. The *message* shall be interpreted using the notation for the *printf* formatting specification; see *printf*. If the *value* field was a string, then the value from the file shall be the argument for the *printf* formatting specification; otherwise, the value from the file shall be the argument.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *file* utility can only be required to guess at many of the file types because only exhaustive testing can determine some types with certainty. For example, binary data on some systems might match the initial segment of an executable or a *tar* archive.

Note that the table indicates that the output contains the stated string. Systems may add text before or after the string. For executables, as an example, the machine architecture and various facts about how the file was link-edited may be included.

EXAMPLES

Determine whether an argument is a binary executable file:

```
file "$1" | grep –Fq executable &&
    printf "%s is executable.\n" "$1"
```

RATIONALE

The **–f** option was omitted because the same effect can (and should) be obtained using the *xargs* utility.

Historical versions of the *file* utility attempt to identify the following types of files: symbolic link, directory, character special, block special, socket, *tar* archive, *cpio* archive, SCCS archive, archive library, empty, *compress* output, *pack* output, binary data, C source, FORTRAN source, assembler source, *nroff* / *troff* / *eqn* / *tbl* source *troff* output, shell script, C shell script, English text, ASCII text, various executables, APL workspace, compiled terminfo entries, and CURSES screen images. Only those types that are reasonably well specified in POSIX or are directly related to POSIX utilities are listed in the table.

Implementations that support symbolic links are encouraged to use the string `"symbolic link"` to identify them.

Historical systems have used a ‘‘magic file’’ named **/etc/magic** to help identify file types. Because it is generally useful for users and scripts to be able to identify special file types, the **–m** flag and a portable format for user-created magic files has been specified. No requirement is made that an implementation of *file* use this method of identifying files, only that users be permitted to add their own classifying tests.

In addition, three options have been added to historical practice. The **–d** flag has been added to permit users to cause their tests to follow any default system tests. The **–i** flag has been added to permit users to test portably for regular files in shell scripts. The **–M** flag has been added to permit users to ignore any default system tests.

The historical **–c** option was omitted as not particularly useful to users or portable shell scripts. In addition, a reasonable implementation of the *file* utility would report any errors found each time the magic file is read.

The historical format of the magic file was the same as that specified by the Rationale in the previous version of IEEE Std. 1003.1-200x for the *offset*, *value*, and *message* fields; however, it used less precise type fields than the format specified by the current normative text. The new type field values are a superset of the historical ones.

The following is an example magic file:

```
0  short     070707              cpio archive
0  short     0143561             Byte-swapped cpio archive
0  string    070707              ASCII cpio archive
0  long      0177555             Very old archive
0  short     0177545             Old archive
0  short     017437              Old packed data
0  string    \037\036            Packed data
0  string    \377\037            Compacted data
0  string    \037\235            Compressed data
>2 byte&0x80 >0                  Block compressed
>2 byte&0x1f x                   %d bits
0  string    \032\001            Compiled Terminfo Entry
0  short     0433                Curses screen image
0  short     0434                Curses screen image
```

```
0  string    <ar>                System V Release 1 archive
0  string    !<arch>\n__.SYMDEF  Archive random library
0  string    !<arch>             Archive
0  string    ARF_BEGARF          PHIGS clear text archive
0  long      0x137A2950          Scalable OpenFont binary
0  long      0x137A2951          Encrypted scalable OpenFont binary
```

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

Options and an EXTENDED DESCRIPTION are added as specified in the IEEE P1003.2b draft standard.

17257 **NAME**

17258 find — find files

17259 **SYNOPSIS**

17260 `find [–H | –L] path ... [operand_expression ...]`

17261 **DESCRIPTION**

17262 The *find* utility shall recursively descend the directory hierarchy from each file specified by *path*,
17263 evaluating a Boolean expression composed of the primaries described in the OPERANDS section
17264 for each file encountered.

17265 The *find* utility shall be able to descend to arbitrary depths in a file hierarchy and shall not fail
17266 due to path length limitations (unless a *path* operand specified by the application exceeds
17267 {PATH_MAX} requirements).

17268 The *find* utility shall detect infinite loops; that is, entering a previously visited directory that is an
17269 ancestor of the last file encountered. When it detects an infinite loop, *find* shall write a
17270 diagnostic message to standard error and shall either recover its position in the hierarchy or
17271 terminate.

17272 **OPTIONS**

17273 The *find* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
17274 12.2, Utility Syntax Guidelines.

17275 The following options shall be supported by the implementation:

17276 **–H** Cause the file information and file type evaluated for each symbolic link
17277 encountered on the command line to be those of the file referenced by the link, and
17278 not the link itself. If the referenced file does not exist, the file information and type
17279 shall be for the link itself. File information for all symbolic links not on the
17280 command line shall be that of the link itself.

17281 **–L** Cause the file information and file type evaluated for each symbolic link to be
17282 those of the file referenced by the link, and not the link itself.

17283 Specifying more than one of the mutually-exclusive options **–H** and **–L** shall not be considered
17284 an error. The last option specified shall determine the behavior of the utility.

17285 **OPERANDS**

17286 The following operands shall be supported:

17287 The *path* operand is a path name of a starting point in the directory hierarchy.

17288 The first argument that starts with a '–', or is a '!' or a '(', and all subsequent arguments
17289 shall be interpreted as an *expression* made up of the following primaries and operators. In the
17290 descriptions, wherever *n* is used as a primary argument, it shall be interpreted as a decimal
17291 integer optionally preceded by a plus ('+') or minus ('–') sign, as follows:

17292 *+n* More than *n*.

17293 *n* Exactly *n*.

17294 *–n* Less than *n*.

17295 The following primaries shall be supported:

17296 **–name** *pattern*
17297 The primary shall evaluate as true if the basename of the file name being examined
17298 matches *pattern* using the pattern matching notation described in Section 2.14 (on
17299 page 2274).

17300 **–nouser** The primary shall evaluate as true if the file belongs to a user ID for which the
17301 *getpwuid*( ) function defined in the System Interfaces volume of
17302 IEEE Std. 1003.1-200x (or equivalent) returns NULL.

17303 **–nogroup** The primary shall evaluate as true if the file belongs to a group ID for which the
17304 *getgrgid*( ) function defined in the System Interfaces volume of
17305 IEEE Std. 1003.1-200x (or equivalent) returns NULL.

17306 **–xdev** The primary always shall evaluate as true; it shall cause *find* not to continue
17307 descending past directories that have a different device ID (*st_dev*, see the *stat*( )
17308 function defined in the System Interfaces volume of IEEE Std. 1003.1-200x). If any
17309 **–xdev** primary is specified, it shall apply to the entire expression even if the **–xdev**
17310 primary would not normally be evaluated.

17311 **–prune** The primary always shall evaluate as true; it shall cause *find* not to descend the
17312 current path name if it is a directory. If the **–depth** primary is specified, the **–prune**
17313 primary shall have no effect.

17314 **–perm [–]***mode*
17315 The *mode* argument is used to represent file mode bits. It shall be identical in
17316 format to the *symbolic_mode* operand described in *chmod* (on page 2450), and shall
17317 be interpreted as follows. To start, a template shall be assumed with all file mode
17318 bits cleared. An *op* symbol of `'+'` shall set the appropriate mode bits in the
17319 template; `'–'` shall clear the appropriate bits; `'='` shall set the appropriate mode
17320 bits, without regard to the contents of process' file mode creation mask. The *op*
17321 symbol of `'–'` cannot be the first character of *mode*; this avoids ambiguity with the
17322 optional leading hyphen. Since the initial mode is all bits off, there are not any
17323 symbolic modes that need to use `'–'` as the first character.

17324 If the hyphen is omitted, the primary shall evaluate as true when the file
17325 permission bits exactly match the value of the resulting template.

17326 Otherwise, if *mode* is prefixed by a hyphen, the primary shall evaluate as true if at
17327 least all the bits in the resulting template are set in the file permission bits.

17328 **–perm [–]***onum*
17329 If the hyphen is omitted, the primary shall evaluate as true when the file
17330 permission bits exactly match the value of the octal number *onum* and only the bits
17331 corresponding to the octal mask 07777 shall be compared. (See the description of
17332 the octal *mode* in *chmod* (on page 2450).) Otherwise, if *onum* is prefixed by a
17333 hyphen, the primary shall evaluate as true if at least all of the bits specified in *onum*
17334 that are also set in the octal mask 07777 are set.

17335 **–type** *c* The primary shall evaluate as true if the type of the file is *c*, where *c* is `'b'`, `'c'`,
17336 `'d'`, `'l'`, `'p'`, `'f'`, or `'s'` for block special file, character special file, directory,
17337 symbolic link, FIFO, regular file, or socket, respectively.

17338 **–links** *n* The primary shall evaluate as true if the file has *n* links.

17339 **–user** *uname* The primary shall evaluate as true if the file belongs to the user *uname*. If *uname* is
17340 a decimal integer and the *getpwnam*( ) (or equivalent) function does not return a
17341 valid user name, *uname* shall be interpreted as a user ID.

17342 **–group** *gname*
17343 The primary shall evaluate as true if the file belongs to the group *gname*. If *gname*
17344 is a decimal integer and the *getgrnam*( ) (or equivalent) function does not return a
17345 valid group name, *gname* shall be interpreted as a group ID.

17346 –**size** *n***[c]** The primary shall evaluate as true if the file size in bytes, divided by 512 and
17347 rounded up to the next integer, is *n*. If *n* is followed by the character 'c', the size
17348 shall be in bytes.

17349 –**atime** *n* The primary shall evaluate as true if the file access time subtracted from the
17350 initialization time, divided by 86 400 (with any remainder discarded), is *n*.

17351 –**ctime** *n* The primary shall evaluate as true if the time of last change of file status
17352 information subtracted from the initialization time, divided by 86 400 (with any
17353 remainder discarded), is *n*.

17354 –**mtime** *n* The primary shall evaluate as true if the file modification time subtracted from the
17355 initialization time, divided by 86 400 (with any remainder discarded), is *n*.

17356 –**exec** *utility_name* **[***argument* ...**] ;**
17357 The primary shall evaluate as true if the invoked utility *utility_name* returns a zero
17358 value as exit status. The end of the primary expression shall be punctuated by a
17359 semicolon. A *utility_name* or *argument* containing only the two characters "{}"
17360 shall be replaced by the current path name. If a *utility_name* or argument string
17361 contains the two characters "{}", but not just the two characters "{}", it is |
17362 implementation-defined whether *find* replaces those two characters with the |
17363 current path name or uses the string without change. The current directory for the
17364 invocation of *utility_name* shall be the same as the current directory when the *find*
17365 utility was started. If the *utility_name* names any of the special built-in utilities in
17366 Section 2.15 (on page 2276), the results are undefined.

17367 –**ok** *utility_name* **[***argument* ...**] ;**
17368 The –**ok** primary shall be equivalent to –**exec**, except that *find* shall request
17369 affirmation of the invocation of *utility_name* using the current file as an argument
17370 by writing to standard error as described in the STDERR section. If the response on
17371 standard input is affirmative, the utility shall be invoked. Otherwise, the command
17372 shall not be invoked and the value of the –**ok** operand shall be false.

17373 –**print** The primary always shall evaluate as true; it shall cause the current path name to
17374 be written to standard output.

17375 –**newer** *file* The primary shall evaluate as true if the modification time of the current file is
17376 more recent than the modification time of the file named by the path name *file*.

17377 –**depth** The primary shall always evaluate as true; it shall cause descent of the directory
17378 hierarchy to be done so that all entries in a directory are acted on before the
17379 directory itself. If a –**depth** primary is not specified, all entries in a directory shall
17380 be acted on after the directory itself. If any –**depth** primary is specified, it shall
17381 apply to the entire expression even if the –**depth** primary would not normally be
17382 evaluated.

17383 The primaries can be combined using the following operators (in order of decreasing
17384 precedence):

17385 (*expression*) True if *expression* is true.

17386 **!** *expression* Negation of a primary; the unary NOT operator.

17387 *expression* **[**–**a]** *expression*
17388 Conjunction of primaries; the AND operator is implied by the juxtaposition of two
17389 primaries or made explicit by the optional –**a** operator. The second expression
17390 shall not be evaluated if the first expression is false.

17391 *expression* **–o** *expression*
17392 Alternation of primaries; the OR operator. The second expression shall not be
17393 evaluated if the first expression is true.

17394 If no *expression* is present, **–print** shall be used as the expression. Otherwise, if the given
17395 expression does not contain any of the primaries **–exec**, **–ok**, or **–print**, the given expression shall
17396 be effectively replaced by:

17397 `( given_expression ) –print`

17398 The **–user**, **–group**, and **–newer** primaries each shall evaluate their respective arguments only
17399 once.

17400 **STDIN**

17401 If the **–ok** primary is used, the response shall be read from the standard input. An entire line
17402 shall be read as the response. Otherwise, the standard input shall not be used.

17403 **INPUT FILES**

17404 None.

17405 **ENVIRONMENT VARIABLES**

17406 The following environment variables shall affect the execution of *find*:

17407 *LANG* Provide a default value for the internationalization variables that are unset or null.
17408 If *LANG* is unset or null, the corresponding value from the implementation-
17409 defined default locale shall be used. If any of the internationalization variables
17410 contains an invalid setting, the utility shall behave as if none of the variables had
17411 been defined.

17412 *LC_ALL* If set to a non-empty string value, override the values of all the other
17413 internationalization variables.

17414 *LC_COLLATE*
17415 Determine the locale for the behavior of ranges, equivalence classes and multi-
17416 character collating elements used in the pattern matching notation for the **–n**
17417 option and in the extended regular expression defined for the **yesexpr** locale
17418 keyword in the *LC_MESSAGES* category.

17419 *LC_CTYPE* This variable determines the locale for the interpretation of sequences of bytes of
17420 text data as characters (for example, single-byte as opposed to multi-byte
17421 characters in arguments), the behavior of character classes within the pattern
17422 matching notation used for the **–n** option, and the behavior of character classes
17423 within regular expressions used in the extended regular expression defined for the
17424 **yesexpr** locale keyword in the *LC_MESSAGES* category.

17425 *LC_MESSAGES*
17426 Determine the locale for the processing of affirmative responses that should be
17427 used to affect the format and contents of diagnostic messages written to standard
17428 error.

17429 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

17430 *PATH* Determine the location of the *utility_name* for the **–exec** and **–ok** primaries, as
17431 described in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8,
17432 Environment Variables.

17433 **ASYNCHRONOUS EVENTS**
17434 Default.

17435 **STDOUT**
17436 The –**print** primary shall cause the current path names to be written to standard output. The
17437 format shall be:

17438 `"%s\n", <path>`

17439 **STDERR**
17440 The –**ok** primary shall write a prompt to standard error containing at least the *utility_name* to be
17441 invoked and the current path name. In the POSIX locale, the last non-<blank> character in the
17442 prompt shall be `'?'`. The exact format used is unspecified.

17443 Otherwise, the standard error shall be used only for diagnostic messages.

17444 **OUTPUT FILES**
17445 None.

17446 **EXTENDED DESCRIPTION**
17447 None.

17448 **EXIT STATUS**
17449 The following exit values shall be returned:

17450 0 All *path* operands were traversed successfully.

17451 >0 An error occurred.

17452 **CONSEQUENCES OF ERRORS**
17453 Default.

17454 **APPLICATION USAGE**
17455 When used in operands, pattern matching notation, semicolons, opening parentheses, and
17456 closing parentheses are special to the shell and must be quoted (see Section 2.2 (on page 2236)).

17457 The bit that is traditionally used for sticky (historically 01000) is specified in the –**perm** primary
17458 using the octal number argument form. Since this bit is not defined by this volume of
17459 IEEE Std. 1003.1-200x, applications must not assume that it actually refers to the traditional
17460 sticky bit.

17461 **EXAMPLES**

17462 1. The following commands are equivalent:

17463 `find .`
17464 `find . –print`

17465 They both write out the entire directory hierarchy from the current directory.

17466 2. The following command:

17467 `find / \( –name tmp –o –name '*.xx' \) –atime +7 –exec rm {} \;`

17468 removes all files named **tmp** or ending in **.xx** that have not been accessed for seven or more
17469 24-hour periods.

17470 3. The following command:

17471 `find . –perm –o+w,+s`

17472 prints (–**print** is assumed) the names of all files in or below the current directory, with all
17473 of the file permission bits S_ISUID, S_ISGID, and S_IWOTH set.

4. The following command:

   ```
   find . –name SCCS –prune –o –print
   ```

   recursively prints path names of all files in the current directory and below, but skips directories named SCCS and files in them.

5. The following command:

   ```
   find . –print –name SCCS –prune
   ```

   behaves as in the previous example, but prints the names of the SCCS directories.

6. The following command is roughly equivalent to the –**nt** extension to *test*:

   ```
   if [ –n "$(find file1 –prune –newer file2)" ]; then
       printf %s\\n "file1 is newer than file2"
   fi
   ```

7. The descriptions of –**atime**, –**ctime**, and –**mtime** use the terminology *n* ‘‘86 400 second periods (days)’’. For example, a file accessed at 23:59 is selected by:

   ```
   find . –atime –1 –print
   ```

   at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

RATIONALE

The –**a** operator was retained as an optional operator for compatibility with historical shell scripts, even though it is redundant with expression concatenation.

The descriptions of the ’–’ modifier on the *mode* and *onum* arguments to the –**perm** primary agree with historical practice on BSD and System V implementations. System V and BSD documentation both describe it in terms of checking additional bits; in fact, it uses the same bits, but checks for having at least all of the matching bits set instead of having exactly the matching bits set.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because:

- Implementations may desire more descriptive prompts than those used on historical implementations.
- Since the historical prompt strings do not terminate with <newline>s, there is no portable way for another program to interact with the prompts of this utility via pipes.

Therefore, an application using this prompting option relies on the system to provide the most suitable dialog directly with the user, based on the general guidelines specified.

The –**name** *file* operand was changed to use the shell pattern matching notation so that *find* is consistent with other utilities using pattern matching.

The –**size** operand refers to the size of a file, rather than the number of blocks it may occupy in the file system. The intent is that the *st_size* field defined in the System Interfaces volume of IEEE Std. 1003.1-200x should be used, not the *st_blocks* found in historical implementations. There are at least two reasons for this:

1. In both System V and BSD, *find* only uses *st_size* in size calculations for the operands specified by this volume of IEEE Std. 1003.1-200x. (BSD uses *st_blocks* only when processing the –**ls** primary.)

2. Users usually think of file size in terms of bytes, which is also the unit used by the *ls* utility for the output from the **–l** option. (In both System V and BSD, *ls* uses *st_size* for the **–l** option size field and uses *st_blocks* for the *ls* **–s** calculations. This volume of IEEE Std. 1003.1-200x does not specify *ls* **–s**.)

The descriptions of **–atime**, **–ctime**, and **–mtime** were changed from the SVID description of *n* ''days'' to ''24-hour periods''. The description is also different in terms of the exact timeframe for the *n* case (*versus* the *+n* or *–n*), but it matches all known historical implementations. It refers to one 86 400 second period in the past, not any time from the beginning of that period to the current time. For example, **–atime** 3 is true if the file was accessed any time in the period from 72 hours to 48 hours ago.

Historical implementations do not modify `"{}"` when it appears as a substring of an **–exec** or **–ok** *utility_name* or argument string. There have been numerous user requests for this extension, so this volume of IEEE Std. 1003.1-200x allows the desired behavior. At least one recent implementation does support this feature, but encountered several problems in managing memory allocation and dealing with multiple occurrences of `"{}"` in a string while it was being developed, so it is not yet required behavior.

Assuming the presence of **–print** was added to correct a historical pitfall that plagues novice users, it is entirely upward-compatible from the historical System V *find* utility. In its simplest form (*find directory*), it could be confused with the historical BSD fast *find*. The BSD developers agreed that adding **–print** as a default expression was the correct decision and have added the fast *find* functionality within a new utility called *locate*.

Historically, the **–L** option was implemented using the primary **–follow**. The **–H** and **–L** options were added for two reasons. First, they offer a finer granularity of control and consistency with other programs that walk file hierarchies. Second, the **–follow** primary always evaluated to true. As they were historically really global variables that took effect before the traversal began, some valid expressions had unexpected results. An example is the expression **–print –o –follow**. Because **–print** always evaluates to true, the standard order of evaluation implies that **–follow** would never be evaluated. This was never the case. Historical practice for the **–follow** primary, however, is not consistent. Some implementations always follow symbolic links on the command line whether **–follow** is specified or not. Others follow symbolic links on the command line only if **–follow** is specified. Both behaviors are provided by the **–H** and **–L** options, but scripts using the current **–follow** primary would be broken if the **–follow** option is specified to work either way.

Since the **–L** option resolves all symbolic links and the **–type** *l* primary is true for symbolic links that still exist after symbolic links have been resolved, the command:

```
find –L . –type l
```

prints a list of symbolic links reachable from the current directory that do not resolve to accessible files.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The –**perm [–]***onum* primary is supported.

The *find* utility is aligned with the IEEE P1003.2b draft standard, to include processing of symbolic links and changes to the description of the **atime**, **ctime**, and **mtime** operands.

NAME

fold — filter for folding lines

SYNOPSIS

```
fold [–bs][–w width][file...]
```

DESCRIPTION

The *fold* utility is a filter that shall fold lines from its input files, breaking the lines to have a maximum of *width* column positions (or bytes, if the **–b** option is specified). Lines shall be broken by the insertion of a <newline> character such that each output line (referred to later in this section as a *segment*) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line shall not be broken in the middle of a character. The behavior is undefined if *width* is less than the number of columns any single character in the input would occupy.

If the <carriage-return>, <backspace>, or <tab> characters are encountered in the input, and the **–b** option is not specified, they shall be treated specially:

<backspace> The current count of line width shall be decremented by one, although the count never shall become negative. The *fold* utility shall not insert a <newline> character immediately before or after any <backspace> character.

<carriage-return>
The current count of line width shall be set to zero. The *fold* utility shall not insert a <newline> character immediately before or after any <carriage-return> character.

<tab> Each <tab> character encountered shall advance the column position pointer to the next tab stop. Tab stops shall be at each column position *n* such that *n* modulo 8 equals 1.

OPTIONS

The *fold* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–b Count *width* in bytes rather than column positions.

–s If a segment of a line contains a <blank> character within the first *width* column positions (or bytes), break the line after the last such <blank> character meeting the width constraints. If there is no <blank> character meeting the requirements, the **–s** option shall have no effect for that output segment of the input line.

–w *width* Specify the maximum line length, in column positions (or bytes if **–b** is specified). The results are unspecified if *width* is not a positive decimal number. The default value shall be 80.

OPERANDS

The following operand shall be supported:

file A path name of a text file to be folded. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

17611 **INPUT FILES**

17612 If the **–b** option is specified, the input files shall be text files except that the lines are not limited
17613 to {LINE_MAX} bytes in length. If the **–b** option is not specified, the input files shall be text files.

17614 **ENVIRONMENT VARIABLES**

17615 The following environment variables shall affect the execution of *fold*:

17616 *LANG* Provide a default value for the internationalization variables that are unset or null.
17617 If *LANG* is unset or null, the corresponding value from the implementation-
17618 defined default locale shall be used. If any of the internationalization variables
17619 contains an invalid setting, the utility shall behave as if none of the variables had
17620 been defined.

17621 *LC_ALL* If set to a non-empty string value, override the values of all the other
17622 internationalization variables.

17623 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
17624 characters (for example, single-byte as opposed to multi-byte characters in
17625 arguments and input files), and for the determination of the width in column
17626 positions each character would occupy on a constant-width font output device.

17627 *LC_MESSAGES*
17628 Determine the locale that should be used to affect the format and contents of
17629 diagnostic messages written to standard error.

17630 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

17631 **ASYNCHRONOUS EVENTS**

17632 Default.

17633 **STDOUT**

17634 The standard output shall be a file containing a sequence of characters whose order shall be
17635 preserved from the input files, possibly with inserted <newline> characters.

17636 **STDERR**

17637 Used only for diagnostic messages.

17638 **OUTPUT FILES**

17639 None.

17640 **EXTENDED DESCRIPTION**

17641 None.

17642 **EXIT STATUS**

17643 The following exit values shall be returned:

17644 0 All input files were processed successfully.

17645 >0 An error occurred.

17646 **CONSEQUENCES OF ERRORS**

17647 Default.

APPLICATION USAGE

The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths. The *cut* utility should be used when the number of lines (or records) needs to remain constant. The *fold* utility should be used when the contents of long lines need to be kept contiguous.

The *fold* utility is frequently used to send text files to printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

EXAMPLES

An example invocation that submits a file of possibly long lines to the printer (under the assumption that the user knows the line width of the printer to be assigned by *lp*):

```
fold –w 132 bigfile | lp
```

RATIONALE

Although terminal input in canonical processing mode requires the erase character (frequently set to <backspace>) to erase the previous character (not byte or column position), terminal output is not buffered and is extremely difficult, if not impossible, to parse correctly; the interpretation depends entirely on the physical device that actually displays/prints/stores the output. In all known internationalized implementations, the utilities producing output for mixed column-width output assume that a <backspace> backs up one column position and outputs enough <backspace>s to return to the start of the character when <backspace> is used to provide local line motions to support underlining and emboldening operations. Since *fold* without the **–b** option is dealing with these same constraints, <backspace> is always treated as backing up one column position rather than backing up one character.

Historical versions of the *fold* utility assumed 1 byte was one character and occupied one column position when written out. This is no longer always true. Since the most common usage of *fold* is believed to be folding long lines for output to limited-length output devices, this capability was preserved as the default case. The **–b** option was added so that applications could *fold* files with arbitrary length lines into text files that could then be processed by the standard utilities. Note that although the width for the **–b** option is in bytes, a line is never split in the middle of a character. (It is unspecified what happens if a width is specified that is too small to hold a single character found in the input followed by a <newline>.)

The tab stops are hardcoded to be every eighth column to meet historical practice. No new method of specifying other tab stops was invented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

17687 **NAME**

17688 fort77 — FORTRAN compiler (**FORTRAN**)

17689 **SYNOPSIS**

17690 FD
```
fort77 [–c][–g][–L directory]... [–O optlevel][–o outfile][–s][–w]
    operand...
```
17691

17692

17693 **DESCRIPTION**

17694 The *fort77* utility is the interface to the FORTRAN compilation system; it shall accept the full
17695 FORTRAN-77 language defined by the ANSI X3.9-1978 standard. The system conceptually
17696 consists of a compiler and link editor. The files referenced by *operand*s are compiled and linked
17697 to produce an executable file. It is unspecified whether the linking occurs entirely within the
17698 operation of *fort77*; some systems may produce objects that are not fully resolved until the file is
17699 executed.

17700 If the **–c** option is present, for all path name operands of the form *file***.f**, the files:

17701 `$(basename` *pathname*`.f).o`

17702 shall be created or overwritten as the result of successful compilation. If the **–c** option is not
17703 specified, it is unspecified whether such **.o** files are created or deleted for the *file***.f** operands.

17704 If there are no options that prevent link editing (such as **–c**) and all operands compile and link
17705 without error, the resulting executable file shall be written into the file named by the **–o** option
17706 (if present) or to the file **a.out**. The executable file shall be created as specified in the System
17707 Interfaces volume of IEEE Std. 1003.1-200x, except that the file permissions shall be set to:

17708 S_IRWXO | S_IRWXG | S_IRWXU

17709 and that the bits specified by the *umask* of the process shall be cleared.

17710 **OPTIONS**

17711 The *fort77* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section |
17712 12.2, Utility Syntax Guidelines, except that: |

17713 • The **–l** *library* operands have the format of options, but their position within a list of
17714 operands affects the order in which libraries are searched.

17715 • The order of specifying the multiple **–L** options is significant.

17716 • Portable applications shall specify each option separately; that is, grouping option letters (for
17717 example, **–cg**) need not be recognized by all implementations.

17718 The following options shall be supported:

17719 **–c** Suppress the link-edit phase of the compilation, and do not remove any object files
17720 that are produced.

17721 **–g** Produce symbolic information in the object or executable files; the nature of this
17722 information is unspecified, and may be modified by implementation-defined |
17723 interactions with other options. |

17724 **–s** Produce object or executable files, or both, from which symbolic and other
17725 information not required for proper execution using the *exec* family of functions
17726 defined in the System Interfaces volume of IEEE Std. 1003.1-200x has been
17727 removed (stripped). If both **–g** and **–s** options are present, the action taken is
17728 unspecified.

17729 **–o** *outfile* Use the path name *outfile*, instead of the default **a.out**, for the executable file
17730 produced. If the **–o** option is present with **–c**, the result is unspecified.

17731 **–L** *directory* Change the algorithm of searching for the libraries named in **–l** operands to look in
17732 the directory named by the *directory* path name before looking in the usual places.
17733 Directories named in **–L** options shall be searched in the specified order. At least
17734 ten instances of this option shall be supported in a single *fort77* command
17735 invocation. If a directory specified by a **–L** option contains a file named **libf.a**, the
17736 results are unspecified.

17737 **–O** *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit
17738 `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the
17739 nature of the optimization is unspecified. If the **–O** option is omitted, the nature of
17740 the system's default optimization is unspecified. It is unspecified whether code
17741 generated in the presence of the **–O** 0 option is the same as that generated when
17742 **–O** is omitted. Other *optlevel* values may be supported.

17743 **–w** Suppress warnings.

17744 Multiple instances of **–L** options can be specified.

17745 **OPERANDS**

17746 An *operand* is either in the form of a path name or the form **–l** *library*. At least one operand of the
17747 path name form shall be specified. The following operands shall be supported:

17748 *file*.**f** The path name of a FORTRAN source file to be compiled and optionally passed to
17749 the link editor. The file name operand shall be of this form if the **–c** option is used.

17750 *file*.**a** A library of object files typically produced by *ar*, and passed directly to the link
17751 editor. Implementations may recognize implementation-defined suffixes other |
17752 than **.a** as denoting object file libraries. |

17753 *file*.**o** An object file produced by *fort77* **–c** and passed directly to the link editor.
17754 Implementations may recognize implementation-defined suffixes other than **.o** as |
17755 denoting object files.

17756 The processing of other files is implementation-defined. |

17757 **–l** *library* (The letter ell.) Search the library named:

17758 `lib`*`library`*`.a`

17759 A library is searched when its name is encountered, so the placement of a **–l**
17760 operand is significant. Several standard libraries can be specified in this manner, as
17761 described in the EXTENDED DESCRIPTION section. Implementations may |
17762 recognize implementation-defined suffixes other than **.a** as denoting libraries. |

17763 **STDIN**

17764 Not used.

17765 **INPUT FILES**

17766 The input file shall be one of the following: a text file containing FORTRAN source code; an
17767 object file in the format produced by *fort77* **–c**; or a library of object files, in the format produced
17768 by archiving zero or more object files, using *ar*. Implementations may supply additional utilities
17769 that produce files in these formats. Additional input files are implementation-defined. |

17770 A <tab> character encountered within the first six characters on a line of source code shall cause
17771 the compiler to interpret the following character as if it were the seventh character on the line
17772 (that is, in column 7).

17773 **ENVIRONMENT VARIABLES**

17774 The following environment variables shall affect the execution of *fort77*:

17775 *LANG* Provide a default value for the internationalization variables that are unset or null.
17776 If *LANG* is unset or null, the corresponding value from the implementation-
17777 defined default locale shall be used. If any of the internationalization variables
17778 contains an invalid setting, the utility shall behave as if none of the variables had
17779 been defined.

17780 *LC_ALL* If set to a non-empty string value, override the values of all the other
17781 internationalization variables.

17782 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
17783 characters (for example, single-byte as opposed to multi-byte characters in
17784 arguments and input files).

17785 *LC_MESSAGES*
17786 Determine the locale that should be used to affect the format and contents of
17787 diagnostic messages written to standard error.

17788 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

17789 *TMPDIR* Determine the path name that should override the default directory for temporary
17790 files, if any.

17791 **ASYNCHRONOUS EVENTS**

17792 Default.

17793 **STDOUT**

17794 Not used.

17795 **STDERR**

17796 Used only for diagnostic messages. If more than one *file* operand ending in **.f** (or possibly other
17797 unspecified suffixes) is given, for each such file:

17798 `"%s:\n", <file>`

17799 may be written to allow identification of the diagnostic message with the appropriate input file.

17800 This utility may produce warning messages about certain conditions that do not warrant
17801 returning an error (non-zero) exit value.

17802 **OUTPUT FILES**

17803 Object files, listing files and executable files shall be produced in unspecified formats.

17804 **EXTENDED DESCRIPTION**

17805 **Standard Libraries**

17806 The *fort77* utility shall recognize the following **–l** operand for the standard library:

17807 **–l f** This library contains all library functions referenced in the ANSI X3.9-1978
17808 standard. This operand shall not be required to be present to cause a search of this
17809 library.

17810 In the absence of options that inhibit invocation of the link editor, such as **–c**, the *fort77* utility
17811 shall cause the equivalent of a **–l f** operand to be passed to the link editor as the last **–l** operand,
17812 causing it to be searched after all other object files and libraries are loaded.

17813 It is unspecified whether the library **libf.a** exists as a regular file. The implementation may
17814 accept as **–l** operands names of objects that do not exist as regular files.

External Symbols

The FORTRAN compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; case folding is permitted. The action taken upon encountering symbols exceeding the implementation-defined maximum symbol length is unspecified.

The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4095 external symbols total. A diagnostic message is written to standard output if the implementation-defined limit is exceeded; other actions are unspecified.

EXIT STATUS

The following exit values shall be returned:

0 Successful compilation or link edit.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When *fort77* encounters a compilation error, it shall write a diagnostic to standard error and continue to compile other source code operands. It shall return a non-zero exit status, but it is implementation-defined whether an object module is created. If the link edit is unsuccessful, a diagnostic message shall be written to standard error, and *fort77* shall exit with a non-zero status.

APPLICATION USAGE

None.

EXAMPLES

The following usage example compiles **xyz.f** and creates the executable file **foo**:

```
fort77 –o foo xyz.f
```

The following example compiles **xyz.f** and creates the object file **xyz.o**:

```
fort77 –c xyz.f
```

The following example compiles **xyz.f** and creates the executable file **a.out**:

```
fort77 xyz.f
```

The following example compiles **xyz.f**, links it with **b.o**, and creates the executable **a.out**:

```
fort77 xyz.f b.o
```

RATIONALE

The name of this utility was chosen as *fort77* to parallel the renaming of the C compiler. The name *f77* was not chosen to avoid problems with historical implementations. The ANSI X3.9-1978 standard was selected as a normative reference because the ISO/IEC version of FORTRAN-77 has been superseded by the ISO/IEC 1539:1990 standard (Fortran-90).

The file inclusion and symbol definition **#define** mechanisms used by the *c99* utility were not included in this volume of IEEE Std. 1003.1-200x—even though they are commonly implemented—since there is no requirement that the FORTRAN compiler use the C preprocessor.

The **–onetrip** option was not included in this volume of IEEE Std. 1003.1-200x, even though many historical compilers support it, because it is derived from FORTRAN-66; it is an anachronism that should not be perpetuated.

Some implementations produce compilation listings. This aspect of FORTRAN has been left unspecified because there was controversy concerning the various methods proposed for implementing it: a **–V** option overlapped with historical vendor practice and a naming

convention of creating files with **.l** suffixes collided with historical *lex* file naming practice.

There is no **–I** option in this version of this volume of IEEE Std. 1003.1-200x to specify a directory for file inclusion. An INCLUDE directive has been a part of the Fortran-90 discussions, but an interface supporting that standard is not in the current scope.

It is noted that many FORTRAN compilers produce an object module even when compilation errors occur; during a subsequent compilation, the compiler may patch the object module rather than recompiling all the code. Consequently, it is left to the implementor whether or not an object file is created.

A reference to MIL-STD-1753 was removed from an early proposal in response to a request from the POSIX FORTRAN-binding standard developers. It was not the intention of the standard developers to require certification of the FORTRAN compiler, and IEEE Std. 1003.9-1992 does not specify the military standard or any special preprocessing requirements. Furthermore, use of that document would have been inappropriate for an international standard.

The specification of optimization has been subject to changes through early proposals. At one time, **–O** and **–N** were Booleans: optimize and do not optimize (with an unspecified default). Some historical practice lead this to be changed to:

–O 0 No optimization.

–O 1 Some level of optimization.

–O *n* Other, unspecified levels of optimization.

It is not always clear whether ‘‘good code generation’’ is the same thing as optimization. Simple optimizations of local actions do not usually affect the semantics of a program. The **–O** 0 option has been included to accommodate the very particular nature of scientific calculations in a highly optimized environment; compilers make errors. Some degree of optimization is expected, even if it is not documented here, and the ability to shut it off completely could be important when porting an application. An implementation may treat **–O** 0 as ‘‘do less than normal’’ if it wishes, but this is only meaningful if any of the operations it performs can affect the semantics of a program. It is highly dependent on the implementation whether doing less than normal is logical. It is not the intent of the **–O** 0 option to ask for inefficient code generation, but rather to assure that any semantically visible optimization is suppressed.

The specification of standard library access is consistent with the C compiler specification. Implementations are not required to have **/usr/lib/libf.a**, as many historical implementations do, but if not they are required to recognize **f** as a token.

External symbol size limits are in normative text; portable applications need to know these limits. However, the minimum maximum symbol length should be taken as a constraint on a portable application, not on an implementation, and consequently the action taken for a symbol exceeding the limit is unspecified. The minimum size for the external symbol table was added for similar reasons.

The CONSEQUENCES OF ERRORS section clearly specifies the behavior of the compiler when compilation or link-edit errors occur. The behavior of several historical implementations was examined, and the choice was made to be silent on the status of the executable, or **a.out**, file in the face of compiler or linker errors. If a linker writes the executable file, then links it on disk with *lseek*( )s and *write*( )s, the partially linked executable file can be left on disk and its execute bits turned off if the link edit fails. However, if the linker links the image in memory before writing the file to disk, it need not touch the executable file (if it already exists) because the link edit fails. Since both approaches are historical practice, a portable application shall rely on the exit status of *fort77*, rather than on the existence or mode of the executable file.

The **–g** and **–s** options are not specified as mutually-exclusive. Historically these two options have been mutually-exclusive, but because both are so loosely specified, it seemed appropriate to leave their interaction unspecified.

The requirement that portable applications specify compiler options separately is to reserve the multi-character option name space for vendor-specific compiler options, which are known to exist in many historical implementations. Implementations are not required to recognize, for example, **–gc** as if it were **–g –c**; nor are they forbidden from doing so. The SYNOPSIS shows all of the options separately to highlight this requirement on applications.

Echoing file names to standard error is considered a diagnostic message because it would otherwise be difficult to associate an error message with the erring file. They are described with ''may'' to allow implementations to use other methods of identifying files and to parallel the description in *c99*.

FUTURE DIRECTIONS

A compilation system based on the ISO/IEC 1539:1990 standard (Fortran-90) may be considered for a future issue; it may have a different utility name from *fort77*.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is now marked as part of the FORTRAN Development Utilities option.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

17926 **NAME**

17927 fuser — list process IDs of all processes that have one or more files open

17928 **SYNOPSIS**

17929 XSI `fuser [ –cfu ] file ...`

17930

17931 **DESCRIPTION**

17932 The *fuser* utility shall write to standard output the process IDs of processes running on the local
17933 system that have one or more named files open. For block special devices, all processes using
17934 any file on that device are listed.

17935 The *fuser* utility shall write to standard error additional information about the named files
17936 indicating how the file is being used.

17937 Any output for processes running on remote systems that have a named file open is unspecified.

17938 A user may need appropriate privilege to invoke the *fuser* utility.

17939 **OPTIONS**

17940 The *fuser* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
17941 12.2, Utility Syntax Guidelines.

17942 The following options shall be supported:

17943 **–c** The file is treated as a mount point and the utility shall report on any files open in
17944 the file system.

17945 **–f** The report shall be only for the named files.

17946 **–u** The user name, in parentheses, associated with each process ID written to standard
17947 output shall be written to standard error.

17948 **OPERANDS**

17949 The following operand shall be supported:

17950 *file* A path name on which the file or file system is to be reported.

17951 **STDIN**

17952 Not used.

17953 **INPUT FILES**

17954 The user database.

17955 **ENVIRONMENT VARIABLES**

17956 The following environment variables shall affect the execution of *fuser*:

17957 *LANG* Provide a default value for the internationalization variables that are unset or null.
17958 If *LANG* is unset or null, the corresponding value from the implementation-
17959 defined default locale shall be used. If any of the internationalization variables
17960 contain an invalid setting, the utility behaves as if none of the variables had been
17961 set.

17962 *LC_ALL* If set to a non-empty string value, override the values of all the other
17963 internationalization variables.

17964 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
17965 characters (for example, single-byte as opposed to multi-byte characters in
17966 arguments).

17967 *LC_MESSAGES*

17968 Determine the locale that should be used to affect the format and contents of

17969 diagnostic messages written to standard error.

17970 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

17971 **ASYNCHRONOUS EVENTS**

17972 Default.

17973 **STDOUT**

17974 The *fuser* utility shall write the process ID for each process using each file given as an operand to
17975 standard output in the following format:

17976 `"%d", <process_id>`

17977 **STDERR**

17978 The *fuser* utility shall write diagnostic messages to standard error.

17979 The *fuser* utility also shall write the following to standard error:

17980 - The path name of each named file is written followed immediately by a colon.

17981 - For each process ID written to standard output, the character `'c'` shall be written to
17982 standard error if the process is using the file as its current directory and the character `'r'`
17983 shall be written to standard error if the process is using the file as its root directory.
17984 Implementations may write other alphabetic characters to indicate other uses of files.

17985 - When the **–u** option is specified, characters indicating the use of the file shall be followed
17986 immediately by the user name, in parentheses, corresponding to the process' real user ID. If
17987 the user name cannot be resolved from the process' real user ID, the process' real user ID
17988 shall be written instead of the user name.

17989 When standard output and standard error are directed to the same file, the output shall be
17990 interspersed so that the file name appears at the start of each line, followed by the process ID
17991 and characters indicating the use of the file. Then, if the **–u** option is specified, the user name or
17992 user ID for each process using that file shall be written.

17993 A <newline> character shall be written to standard error after the last output described above
17994 for each *file* operand.

17995 **OUTPUT FILES**

17996 None.

17997 **EXTENDED DESCRIPTION**

17998 None.

17999 **EXIT STATUS**

18000 The following exit values shall be returned:

18001 0 Successful completion.

18002 >0 An error occurred.

18003 **CONSEQUENCES OF ERRORS**

18004 Default.

18005 **APPLICATION USAGE**

18006 None.

18007 **EXAMPLES**

18008 The command:

18009 `fuser –fu .`

18010 writes to standard output the process IDs of processes that are using the current directory and
18011 writes to standard error an indication of how those processes are using the directory and the
18012 user names associated with the processes that are using the current directory.

18013 **RATIONALE**

18014 None.

18015 **FUTURE DIRECTIONS**

18016 None.

18017 **SEE ALSO**

18018 None.

18019 **CHANGE HISTORY**

18020 First released in Issue 5.

NAME

gencat — generate a formatted message catalog

SYNOPSIS

XSI
```
gencat catfile msgfile...
```

DESCRIPTION

The *gencat* utility shall merge the message text source files *msgfile* into a formatted message catalog *catfile*. The file *catfile* shall be created if it does not already exist. If *catfile* does exist, its messages shall be included in the new *catfile*. If set and message numbers collide, the new message text defined in *msgfile* shall replace the old message text currently contained in *catfile*.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

catfile A path name of the formatted message catalog. If '−' is specified, standard output shall be used. The format of the message catalog produced is unspecified.

msgfile A path name of a message text source file. If '−' is specified for an instance of *msgfile*, standard input shall be used. The format of message text source files is defined in the EXTENDED DESCRIPTION section.

STDIN

The standard input shall not be used unless a *msgfile* operand is specified as '−'.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *gencat*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall not be used unless the *catfile* operand is specified as '−'.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The application shall ensure that the format of a message text source file is defined as follows. Note that the fields of a message text source line are separated by a single <blank> character. Any other <blank> characters are considered as being part of the subsequent field.

$set *n comment*

This line specifies the set identifier of the following messages until the next **$set** or end-of-file appears. The *n* denotes the set identifier, which is defined as a number in the range [1, {NL_SETMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std. 1003.1-200x). The application shall ensure that set identifiers are presented in ascending order within a single source file, but need not be contiguous. Any string following the set identifier shall be treated as a comment. If no **$set** directive is specified in a message text source file, all messages shall be located in an implementation-defined default message set NL_SETD (see the **<nl_types.h>** header defined in the System Interfaces volume of IEEE Std. 1003.1-200x).

$delset *n comment*

This line deletes message set *n* from an existing message catalog. The *n* denotes the set number [1, {NL_SETMAX}]. Any string following the set number shall be treated as a comment.

$ *comment* A line beginning with '$' followed by a <blank> character shall be treated as a comment.

m message-text

The *m* denotes the message identifier, which is defined as a number in the range [1, {NL_MSGMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std. 1003.1-200x). The *message-text* shall be stored in the message catalog with the set identifier specified by the last **$set** directive, and with message identifier *m*. If the *message-text* is empty, and a <blank> character field separator is present, an empty string shall be stored in the message catalog. If a message source line has a message number, but neither a field separator nor *message-text*, the existing message with that number (if any) shall be deleted from the catalog. The application shall ensure that message identifiers are in ascending order within a single set, but need not be contiguous. The application shall ensure that the length of *message-text* is in the range [0, {NL_TEXTMAX}] (see the **<limits.h>** header defined in the System Interfaces volume of IEEE Std. 1003.1-200x).

$quote *n* This line specifies an optional quote character *c*, which can be used to surround *message-text* so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty **$quote** directive is supplied, no quoting of *message-text* shall be recognized.

Empty lines in a message text source file shall be ignored. The effects of lines starting with any character other than those defined above are implementation-defined.

Text strings can contain the special characters and escape sequences defined in the following table:

Description	Symbol	Sequence
<newline>	NL(LF)	\n
Horizontal tab	HT	\t
<vertical-tab>	VT	\v
<backspace>	BS	\b
<carriage-return>	CR	\r
<form-feed>	FF	\f
Backslash	\	\\
Bit pattern	ddd	\ddd

The escape sequence "\ddd" consists of backslash followed by one, two, or three octal digits, which shall be taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash shall be ignored.

Backslash ('\') followed by a <newline> character is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which is equivalent to:

```
1 This line continues to the next line
```

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Message catalogs produced by *gencat* are binary encoded, meaning that their portability cannot be guaranteed between different types of machine. Thus, just as C programs need to be recompiled for each type of machine, so message catalogs must be recreated via *gencat*.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

get — get a version of an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
get [–begkmlLpst][–c cutoff][–i list][–r SID][–x list] file...
```

DESCRIPTION

The *get* utility shall generate a text file from each named SCCS *file* according to the specifications given by its options.

The generated text is normally written into a file called the **g-file** whose name is derived from the SCCS file name by simply removing the leading "s.".

OPTIONS

The *get* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–r *SID* Indicate the SCCS Identification String (SID) of the version (delta) of an SCCS file to be retrieved. The table shows, for the most useful cases, what version of an SCCS file is retrieved (as well as the SID of the version to be eventually created by *delta* if the **–e** option is also used), as a function of the SID specified.

–c *cutoff* Indicate the *cutoff* date-time, in the form:

YY[*MM*[*DD*[*HH*[*MM*[*SS*]]]]]

For the *YY* component, values in the range [69-99] shall refer to years in the twentieth century (1969 to 1999 inclusive); values in the range [00-68] shall refer to years in the twenty-first century (2000 to 2068 inclusive).

No changes (deltas) to the SCCS file that were created after the specified *cutoff* date-time are included in the generated text file. Units omitted from the date-time default to their maximum possible values; for example, **–c 7502** is equivalent to **–c 750228235959**.

Any number of non-numeric characters may separate the various 2-digit pieces of the *cutoff* date-time. This feature allows the user to specify a *cutoff* date in the form: **–c** "77/2/2 9:22:25".

–e Indicate that the *get* is for the purpose of editing or making a change (delta) to the SCCS file via a subsequent use of *delta*. The **–e** option used in a *get* for a particular version (SID) of the SCCS file shall prevent further *get* commands from editing on the same SID until *delta* is executed or the **j** (joint edit) flag is set in the SCCS file. Concurrent use of *get* **–e** for different SIDs is always allowed.

If the **g-file** generated by *get* with a **–e** option is accidentally ruined in the process of editing, it may be regenerated by re-executing the *get* command with the **–k** option in place of the **–e** option.

SCCS file protection specified via the ceiling, floor, and authorized user list stored in the SCCS file shall be enforced when the **–e** option is used.

–b Use with the **–e** option to indicate that the new delta should have an SID in a new branch as shown in the table below. This option shall be ignored if the **b** flag is not present in the file or if the retrieved delta is not a leaf delta. (A leaf delta is one that has no successors on the SCCS file tree.)

Note: A branch delta may always be created from a non-leaf delta.

–i *list* Indicate a *list* of deltas to be included (forced to be applied) in the creation of the generated file. The *list* has the following syntax:

```
<list> ::= <range> | <list> , <range>
<range> ::= SID | SID – SID
```

SID, the SCCS Identification of a delta, may be in any form shown in the ''SID Specified'' column of the table in the EXTENDED DESCRIPTION section. Partial SIDs are interpreted as shown in the ''SID Retrieved'' column of the table.

–x *list* Indicate a *list* of deltas to be excluded (forced not to be applied) in the creation of the generated file. See the **–i** option for the *list* format.

–k Suppress replacement of identification keywords (see below) in the retrieved text by their value. The **–k** option is implied by the **–e** option.

–l Write a delta summary into an **l-file**.

–L Write a delta summary to standard output. All informative output that normally is written to standard output shall be written to standard error instead, unless the **–s** option is used, in which case it shall be suppressed.

–p Write the text retrieved from the SCCS file to the standard output. No **g-file** shall be created. All informative output that normally goes to the standard output shall go to standard error instead, unless the **–s** option is used, in which case it disappears.

–s Suppress all informative output normally written to standard output. However, fatal error messages (which shall always be written to the standard error) remain unaffected.

–m Precede each text line retrieved from the SCCS file by the SID of the delta that inserted the text line in the SCCS file. The format is:

```
"%s\t%s", <SID>, <text line>
```

–n Precede each generated text line with the %**M**% identification keyword value (see below). The format is:

```
"%s\t%s", <%M% value>, <text line>
```

When both the **–m** and **–n** options are used, the <*text line*> shall be replaced by the **–m** option-generated format.

–g Suppress the actual retrieval of text from the SCCS file. It is primarily used to generate an **l-file**, or to verify the existence of a particular SID.

–t Use to access the most recently created (top) delta in a given release (for example, **–r 1**), or release and level (for example, **–r 1.2**).

OPERANDS

The following operands shall be supported:

file A path name of an existing SCCS file or a directory. If *file* is a directory, the *get* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s.**) and unreadable files shall be silently ignored.

If a single instance *file* is specified as '–', the standard input is read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-

SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only if the *file* operand is specified as '−'. Each line of the text file shall be interpreted as an SCCS path name.

INPUT FILES

The SCCS files are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *get*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output (or standard error, if the **−p** option is used).

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

For each file processed, *get* shall write to standard output the SID being accessed and the number of lines retrieved from the SCCS file, in the following format:

"%s\n%d lines\n", <*SID*>, <*number of lines*>

If the **−e** option is used, the SID of the delta to be made shall appear after the SID accessed and before the number of lines generated, in the POSIX locale:

"%s\nnew delta %s\n%d\n", <*SID accessed*>, <*SID to be made*>,
    <*number of lines*>

If there is more than one named file or if a directory or standard input is named, each path name shall be written before each of the lines shown in one of the preceding formats:

"\n%s:\n", <*pathname*>

If the **−L** option is used, a delta summary shall be written following the format specified below for **l-files**.

If the **−i** option is used, included deltas are listed following the notation, in the POSIX locale:

"Included:\n"

If the **−x** option is used, excluded deltas are listed following the notation, in the POSIX locale:

18282 `"Excluded:\n"`

18283 If the –**p** or –**L** options are specified, the standard output consists of the text retrieved from the
18284 SCCS file.

18285 **STDERR**

18286 The standard error shall be used only for diagnostic messages, except if the –**p** or –**L** options are
18287 specified, it includes all informative messages normally sent to standard output.

18288 **OUTPUT FILES**

18289 Several auxiliary files may be created by *get*. These files are known generically as the **g-file**, **l-**
18290 **file**, **p-file**, and **z-file**. The letter before the hyphen is called the *tag*. An auxiliary file name is
18291 formed from the SCCS file name: the application shall ensure that the last component of all
18292 SCCS file names is of the form **s.***module-name*; the auxiliary files are named by replacing the
18293 leading **s** with the tag. The **g-file** is an exception to this scheme: the **g-file** is named by removing
18294 the **s.** prefix. For example, for **s.xyz.c**, the auxiliary file names would be **xyz.c**, **l.xyz.c**, **p.xyz.c**,
18295 and **z.xyz.c**, respectively.

18296 The **g-file**, which contains the generated text, is created in the current directory (unless the –**p**
18297 option is used). A **g-file** is created in all cases, whether or not any lines of text were generated by
18298 the *get*. It is owned by the real user. If the –**k** option is used or implied, it is writable by the
18299 owner only (read-only for everyone else); otherwise, it is read-only. Only the real user need have
18300 write permission in the current directory.

18301 The **l-file** contains a table showing which deltas were applied in generating the retrieved text.
18302 The **l-file** is created in the current directory if the –**l** option is used; it is read-only and it is
18303 owned by the real user. Only the real user need have write permission in the current directory.

18304 Lines in the **l-file** have the following format:

18305 `"%c%c%c␣%s\t%s␣%s\n", <code1>, <code2>, <code3>,`
18306 `<SID>, <date-time>, <login>`

18307 where the entries are:

18308 *<code1>* A <space> character if the delta was applied; `'*'` otherwise.

18309 *<code2>* A <space> character if the delta was applied or was not applied and ignored; `'*'`
18310 if the delta was not applied and was not ignored.

18311 *<code3>* A character indicating a special reason why the delta was or was not applied:

18312 **I** Included.

18313 **X** Excluded.

18314 **C** Cut off (by a –**c** option).

18315 *<date-time>* Date and time (using the *date* utility's %*y* / %*m* / %*d* %*T* format) of creation.

18316 *<login>* Login name of person who created *delta*.

18317 The comments and MR data shall follow on subsequent lines, indented one <tab> character. A
18318 blank line terminates each entry.

18319 The **p-file** is used to pass information resulting from a *get* with a –**e** option along to *delta*. Its
18320 contents are also used to prevent a subsequent execution of *get* with a –**e** option for the same SID
18321 until *delta* is executed or the joint edit flag, **j**, is set in the SCCS file. The **p-file** shall be created in
18322 the directory containing the SCCS file and the application shall ensure that the effective user has
18323 write permission in that directory. It is writable by owner only, and it is owned by the effective
18324 user. Each line in the **p-file** has the following format:

18325 "%sΔ%sΔ%sΔ%s%s%s\n", <*g-file SID*>,
18326 <*SID of new delta*>, <*login-name of real user*>,
18327 <*date-time*>, <*i-value*>, <*x-value*>

18328 where <*i-value*> uses the format " " if no **–i** option was specified, and uses the format:

18329 "Δ–i%s", <–i option *option-argument*>

18330 if a **–i** option was specified and <*x-value*> uses the format " " if no **–x** option was specified, and
18331 uses the format:

18332 "Δ–x%s", <–x option *option-argument*>

18333 if a **–x** option was specified. There can be an arbitrary number of lines in the **p-file** at any time;
18334 no two lines can have the same new delta SID.

18335 The **z-file** serves as a lock-out mechanism against simultaneous updates. Its contents are the
18336 binary process ID of the command (that is, *get*) that created it. The **z-file** is created in the
18337 directory containing the SCCS file for the duration of *get*. The same protection restrictions as
18338 those for the **p-file** apply for the **z-file**. The **z-file** shall be created read-only.

18339 **EXTENDED DESCRIPTION**

18340 **Determination of SCCS Identification String**

18341 18342 SID* Specified	–b Keyletter Used†	Other Conditions	SID Retrieved	SID of Delta to be Created
18343 none‡	no	R defaults to mR	mR.mL	mR.(mL+1)
18344 none‡	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
18345 R	no	R > mR	mR.mL	R.1***
18346 R	no	R = mR	mR.mL	mR.(mL+1)
18347 R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
18348 R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
18349 18350 R	–	R < mR and R does not exist	hR.mL**	hR.mL.(mB+1).1
18351 18352 R	–	Trunk successor in release > R and R exists	R.mL	R.mL.(mB+1).1
18353 R.L	no	No trunk successor	R.L	R.(L+1)
18354 R.L	yes	No trunk successor	R.L	R.L.(mB+1).1
18355 18356 R.L	–	Trunk successor in release ≥ R	R.L	R.L.(mB+1).1
18357 R.L.B	no	No branch successor	R.L.B.mS	R.L.B.(mS+1)
18358 R.L.B	yes	No branch successor	R.L.B.mS	R.L.(mB+1).1
18359 R.L.B.S	no	No branch successor	R.L.B.S	R.L.B.(S+1)
18360 R.L.B.S	yes	No branch successor	R.L.B.S	R.L.(mB+1).1
18361 R.L.B.S	–	Branch successor	R.L.B.S	R.L.(mB+1).1

18362 * R, L, B, and S are the release, level, branch, and sequence components of the SID,
18363 respectively; m means maximum. Thus, for example, R.mL means ‘‘the maximum level
18364 number within release R’’; R.L.(mB+1).1 means ‘‘the first sequence number on the new
18365 branch (that is, maximum branch number plus one) of level L within release R’’. Note
18366 that if the SID specified is of the form R.L, R.L.B, or R.L.B.S, each of the specified
18367 components shall exist.

18368 ** hR is the highest existing release that is lower than the specified, nonexistent, release R.

18369 *** This is used to force creation of the first delta in a new release.

18370 † The –**b** option is effective only if the **b** flag is present in the file. An entry of '–' means
18371 ''irrelevant''.

18372 ‡ This case applies if the **d** (default SID) flag is not present in the file. If the **d** flag is
18373 present in the file, then the SID obtained from the **d** flag is interpreted as if it had been
18374 specified on the command line. Thus, one of the other cases in this table applies.

18375 **Identification Keywords**

18376 Identifying information shall be inserted into the text retrieved from the SCCS file by replacing |
18377 identification keywords with their value wherever they occur. The following keywords may be |
18378 used in the text stored in an SCCS file:

18379 %**M**% Module name: either the value of the **m** flag in the file, or if absent, the name of the
18380 SCCS file with the leading **s.** removed.

18381 %**I**% SCCS identification (SID) (%*R*%.%*L*% or %*R*%.%*L*%.%*B*%.%*S*%) of the retrieved
18382 text.

18383 %**R**% Release.

18384 %**L**% Level.

18385 %**B**% Branch.

18386 %**S**% Sequence.

18387 %**D**% Current date (*YY*/*MM*/*DD*).

18388 %**H**% Current date (*MM*/*DD*/*YY*).

18389 %**T**% Current time (*HH*:*MM*:*SS*).

18390 %**E**% Date newest applied delta was created (*YY*/*MM*/*DD*).

18391 %**G**% Date newest applied delta was created (*MM*/*DD*/*YY*).

18392 %**U**% Time newest applied delta was created (*HH*:*MM*:*SS*).

18393 %**Y**% Module type: value of the **t** flag in the SCCS file.

18394 %**F**% SCCS file name.

18395 %**P**% SCCS absolute path name.

18396 %**Q**% The value of the **q** flag in the file.

18397 %**C**% Current line number. This keyword is intended for identifying messages output by
18398 the program, such as ''this should not have happened'' type errors. It is not
18399 intended to be used on every line to provide sequence numbers.

18400 %**Z**% The four-character string `"@(#)"` recognizable by *what*.

18401 %**W**% A shorthand notation for constructing *what* strings:

18402 `%W%=%Z%%M%<tab>%I%`

18403 %**A**% Another shorthand notation for constructing *what* strings:

18404 `%A%=%Z%%Y%%M%%I%%Z%`

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

The **–lp** option may be withdrawn in a future issue.

SEE ALSO

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Exceptions to Utility Syntax Guidelines conformance noted.

Internationalized environment variable support mandated.

Issue 5

Correction to the first format string in STDOUT.

The interpretation of the *YY* component of the **–c** *cutoff* argument is noted.

Issue 6

The obsolescent SYNOPSIS is removed, removing the **–lp** option.

The Open Group corrigenda item U025/5 has been applied, correcting text in the OPTIONS section.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements.

The Open Group corrigenda item U048/1 has been applied.

18437 **NAME**

18438 getconf — get configuration values

18439 **SYNOPSIS**

18440 `getconf [ –v specification ] system_var` |

18441 `getconf [ –v specification ] path_var pathname` |

18442 **DESCRIPTION** |

18443 In the first synopsis form, the *getconf* utility shall write to the standard output the value of the
18444 variable specified by the *system_var* operand.

18445 In the second synopsis form, the *getconf* utility shall write to the standard output the value of the
18446 variable specified by the *path_var* operand for the path specified by the *pathname* operand.

18447 The value of each configuration variable shall be determined as if it were obtained by calling the
18448 function from which it is defined to be available by this volume of IEEE Std. 1003.1-200x or by
18449 the System Interfaces volume of IEEE Std. 1003.1-200x (see the OPERANDS section). The value
18450 shall reflect conditions in the current operating environment.

18451 **OPTIONS**

18452 The *getconf* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section |
18453 12.2, Utility Syntax Guidelines. |

18454 The following option shall be supported:

18455 **–v** *specification* |

18456 Indicate a specific specification and version for which configuration variables shall |
18457 be determined. If this option is not specified, the values returned correspond to an
18458 implementation default conforming compilation environment.

18459 If the command:

18460 `getconf _POSIX_V6_ILP32_OFF32`

18461 does not write "–1\n" or "undefined\n" to standard output, then commands of
18462 the form:

18463 `getconf –v POSIX_V6_ILP32_OFF32 ...`

18464 determine values for configuration variables corresponding to the |
18465 POSIX_V6_ILP32_OFF32 compilation environment specified in *c99* (on page 2425), |
18466 EXTENDED DESCRIPTION.

18467 If the command:

18468 `getconf _POSIX_V6_ILP32_OFFBIG`

18469 does not write "–1\n" or "undefined\n" to standard output, then commands of
18470 the form:

18471 `getconf –v POSIX_V6_ILP32_OFFBIG ...`

18472 determine values for configuration variables corresponding to the |
18473 POSIX_V6_ILP32_OFFBIG compilation environment specified in *c99* (on page |
18474 2425), EXTENDED DESCRIPTION. |

18475 If the command:

18476 `getconf _POSIX_V6_LP64_OFF64`

18477 does not write "–1\n" or "undefined\n" to standard output, then commands of
18478 the form:

18479 `getconf –v POSIX_V6_LP64_OFF64 ...`

18480 determine values for configuration variables corresponding to the
18481 POSIX_V6_LP64_OFF64 compilation environment specified in *c99* (on page 2425),
18482 EXTENDED DESCRIPTION.

18483 If the command:

18484 `getconf _POSIX_V6_LPBIG_OFFBIG`

18485 does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of
18486 the form:

18487 `getconf –v POSIX_V6_LPBIG_OFFBIG ...`

18488 determine values for configuration variables corresponding to the
18489 POSIX_V6_LPBIG_OFFBIG compilation environment specified in *c99* (on page
18490 2425), EXTENDED DESCRIPTION.

18491 **OPERANDS**

18492 The following operands shall be supported:

18493 *path_var* A name of a configuration variable. All of the variables in the *pathconf*( ) function
18494 defined in the System Interfaces volume of IEEE Std. 1003.1-200x are supported
18495 and the implementation may add other local variables.

18496 *pathname* A path name for which the variable specified by *path_var* is to be determined.

18497 *system_var* A name of a configuration variable. All of the variables in the *confstr*( ) and
18498 *sysconf*( ) functions defined in the System Interfaces volume of
18499 IEEE Std. 1003.1-200x shall be supported and the implementation may add other
18500 local values.

18501 When the symbol listed in the first column of the following table is used as the
18502 *system_var* operand, *getconf* yields the same value as *confstr*( ) when called with the
18503 value in the second column:

18504

18505

system_var	*confstr*() Name Value
PATH	_CS_PATH
POSIX_V6_ILP32_OFF32_CFLAGS	_CS_POSIX_V6_ILP32_OFF32_CFLAGS

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getconf*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the specified variable is defined on the system and its value is described to be available from the *confstr*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, its value shall be written in the following format:

"%s\n", <*value*>

Otherwise, if the specified variable is defined on the system, its value shall be written in the following format:

`"%d\n", <value>`

If the specified variable is valid, but is undefined on the system, *getconf* shall write using the following format:

`"undefined\n"`

If the variable name is invalid or an error occurs, nothing shall be written to standard output.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The specified variable is valid and information about its current state was written successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The following example illustrates the value of {NGROUPS_MAX}:

```
getconf NGROUPS_MAX
```

The following example illustrates the value of {NAME_MAX} for a specific directory:

```
getconf NAME_MAX /usr
```

The following example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
    if [ "$value" = "undefined" ]; then
        echo PATH_MAX in /usr is infinite.
    else
        echo PATH_MAX in /usr is $value.
    fi
else
    echo Error in getconf.
fi
```

Note that:

```
sysconf(_SC_POSIX_C_BIND);
```

and:

```
system("getconf POSIX2_C_BIND");
```

in a C program could give different answers. The *sysconf*( ) call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the *system*( ) call to *getconf* always supplies a value corresponding to conditions when the program is executed.

RATIONALE

The original need for this utility, and for the *confstr*( ) function, was to provide a way of finding the configuration-defined default value for the *PATH* environment variable. Since *PATH* can be modified by the user to include directories that could contain utilities replacing the standard utilities, shell scripts need a way to determine the system-supplied *PATH* environment variable value that contains the correct search path for the standard utilities. It was later suggested that access to the other variables described in this volume of IEEE Std. 1003.1-200x could also be useful to applications.

This functionality of *getconf* would not be adequately subsumed by another command such as:

```
grep var /etc/conf
```

because such a strategy would provide correct values for neither those variables that can vary at runtime, nor those that can vary depending on the path.

Early proposal versions of *getconf* specified exit status 1 when the specified variable was valid, but not defined on the system. The output string `"undefined"` is now used to specify this case with exit code 0 because so many things depend on an exit code of zero when an invoked utility is successful.

FUTURE DIRECTIONS

None.

SEE ALSO

c99, the System Interfaces volume of IEEE Std. 1003.1-200x, *confstr*( ), *pathconf*( ), *sysconf*( )

CHANGE HISTORY

First released in Issue 4.

Issue 4, Version 2

The following changes are made in the table of values for *system_var*:

- Names beginning with POSIX_ are changed to begin with _POSIX_.
- Names beginning with XOPEN_ are changed to begin with _XOPEN_.
- {MN_NMAX} is changed to {NL_MAX}.
- {NL_SET_MAX} is changed to {NL_SETMAX}.
- {NL_TEXT_MAX} is changed to {NL_TEXTMAX}.
- The _XOPEN_CRYPT, _XOPEN_ENH_I18N, and _XOPEN_SHM configuration variables are added to the list.

Issue 5

In the OPERANDS section:

- {NL_MAX} is changed to {NL_NMAX}.
- Entries beginning NL_ are deleted from the list of standard configuration variables.
- The list of variables previously marked UX is merged with the list marked EX.

- Operands are added to support new Option Groups.
- Operands are added so that *getconf* can determine supported programming environments.

Issue 6

The Open Group corrigenda item U029/4 has been applied, correcting the example command in the last paragraph of the OPTIONS section.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Operands are added to determine supported programming environments.

This reference page is updated for alignment with the ISO/IEC 9899:1999 standard. Specifically, new macros for *c99* programming environments are introduced.

18659 **NAME**

18660 getopts — parse utility options

18661 **SYNOPSIS**

18662 `getopts` *optstring name* [*arg...*]

18663 **DESCRIPTION**

18664 The *getopts* utility can be used to retrieve options and option-arguments from a list of
18665 parameters. It shall support the Utility Syntax Guidelines 3 to 10, inclusive, described in the Base
18666 Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

18667 Each time it is invoked, the *getopts* utility shall place the value of the next option in the shell
18668 variable specified by the *name* operand and the index of the next argument to be processed in the
18669 shell variable *OPTIND*. Whenever the shell is invoked, *OPTIND* shall be initialized to 1.

18670 When the option requires an option-argument, the *getopts* utility shall place it in the shell
18671 variable *OPTARG*. If no option was found, or if the option that was found does not have an
18672 option-argument, *OPTARG* shall be unset.

18673 If an option character not contained in the *optstring* operand is found where an option character
18674 is expected, the shell variable specified by *name* shall be set to the question-mark (`'?'`) character.
18675 In this case, if the first character in *optstring* is a colon (`':'`), the shell variable *OPTARG* shall be
18676 set to the option character found, but no output shall be written to standard error; otherwise, the
18677 shell variable *OPTARG* shall be unset and a diagnostic message shall be written to standard
18678 error. This condition shall be considered to be an error detected in the way arguments were
18679 presented to the invoking application, but shall be not an error in *getopts* processing.

18680 If an option-argument is missing:

18681 • If the first character of *optstring* is a colon, the shell variable specified by *name* shall be set to
18682 the colon character and the shell variable *OPTARG* shall be set to the option character found.

18683 • Otherwise, the shell variable specified by *name* shall be set to the question-mark character,
18684 the shell variable *OPTARG* shall be unset, and a diagnostic message shall be written to
18685 standard error. This condition shall be considered to be an error detected in the way
18686 arguments were presented to the invoking application, but shall not be an error in *getopts*
18687 processing; a diagnostic message shall be written as stated, but the exit status shall be zero.

18688 When the end of options is encountered, the *getopts* utility shall exit with a return value greater
18689 than zero; the shell variable *OPTIND* shall be set to the index of the first non-option-argument,
18690 where the first "--" argument is considered to be an option-argument if there are no other non-
18691 option-arguments appearing before it, or the value "$#"+1 if there are no non-option-
18692 arguments; the *name* variable shall be set to the question-mark character. Any of the following
18693 shall identify the end of options: the special option "--", finding an argument that does not
18694 begin with a `'-'`, or encountering an error.

18695 The shell variables *OPTIND* and *OPTARG* shall be local to the caller of *getopts* and shall not be
18696 exported by default.

18697 The shell variable specified by the *name* operand, *OPTIND* and *OPTARG* shall affect the current
18698 shell execution environment; see Section 2.13 (on page 2273).

18699 If the application sets *OPTIND* to the value 1, a new set of parameters can be used: either the
18700 current positional parameters or new *arg* values. Any other attempt to invoke *getopts* multiple
18701 times in a single shell execution environment with parameters (positional parameters or *arg*
18702 operands) that are not the same in all invocations, or with an *OPTIND* value modified to be a
18703 value other than 1, produces unspecified results.

18704 **OPTIONS**

18705 None.

18706 **OPERANDS**

18707 The following operands shall be supported:

18708 *optstring* A string containing the option characters recognized by the utility invoking *getopts*.
18709 If a character is followed by a colon, the option shall be expected to have an
18710 argument, which should be supplied as a separate argument. Applications should
18711 specify an option character and its option-argument as separate arguments, but
18712 *getopts* shall interpret the characters following an option character requiring
18713 arguments as an argument whether or not this is done. An explicit null option-
18714 argument need not be recognized if it is not supplied as a separate argument when
18715 *getopts* is invoked. (See also the *getopt*( ) function defined in the System Interfaces
18716 volume of IEEE Std. 1003.1-200x.) The characters question-mark and colon shall
18717 not be used as option characters by an application. The use of other option
18718 characters that are not alphanumeric produces unspecified results. If the option-
18719 argument is not supplied as a separate argument from the option character, the
18720 value in *OPTARG* shall be stripped of the option character and the '–'. The first
18721 character in *optstring* determines how *getopts* behaves if an option character is not
18722 known or an option-argument is missing.

18723 *name* The name of a shell variable that shall be set by the *getopts* utility to the option
18724 character that was found.

18725 The *getopts* utility by default shall parse positional parameters passed to the invoking shell
18726 procedure. If *arg*s are given, they shall be parsed instead of the positional parameters.

18727 **STDIN**

18728 Not used.

18729 **INPUT FILES**

18730 None.

18731 **ENVIRONMENT VARIABLES**

18732 The following environment variables shall affect the execution of *getopts*:

18733 *LANG* Provide a default value for the internationalization variables that are unset or null.
18734 If *LANG* is unset or null, the corresponding value from the implementation-
18735 defined default locale shall be used. If any of the internationalization variables
18736 contains an invalid setting, the utility shall behave as if none of the variables had
18737 been defined.

18738 *LC_ALL* If set to a non-empty string value, override the values of all the other
18739 internationalization variables.

18740 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
18741 characters (for example, single-byte as opposed to multi-byte characters in
18742 arguments and input files).

18743 *LC_MESSAGES*
18744 Determine the locale that should be used to affect the format and contents of
18745 diagnostic messages written to standard error.

18746 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

18747 *OPTIND* This variable shall be used by the *getopts* utility as the index of the next argument
18748 to be processed.

18749 **ASYNCHRONOUS EVENTS**
18750 Default.

18751 **STDOUT**
18752 Not used.

18753 **STDERR**
18754 Whenever an error is detected and the first character in the *optstring* operand is not a colon
18755 (':'), a diagnostic message shall be written to standard error with the following information in
18756 an unspecified format:

18757 • The invoking program name shall be identified in the message. The invoking program name
18758 shall be the value of the shell special parameter 0 (see Section 2.5.2 (on page 2241)) at the time
18759 the *getopts* utility is invoked. A name equivalent to:

18760 `basename "$0"`

18761 may be used.

18762 • If an option is found that was not specified in *optstring*, this error is identified and the invalid
18763 option character shall be identified in the message.

18764 • If an option requiring an option-argument is found, but an option-argument is not found,
18765 this error shall be identified and the invalid option character shall be identified in the
18766 message.

18767 **OUTPUT FILES**
18768 None.

18769 **EXTENDED DESCRIPTION**
18770 None.

18771 **EXIT STATUS**
18772 The following exit values shall be returned:

18773 0 An option, specified or unspecified by *optstring*, was found.

18774 >0 The end of options was encountered or an error occurred.

18775 **CONSEQUENCES OF ERRORS**
18776 Default.

18777 **APPLICATION USAGE**
18778 Since *getopts* affects the current shell execution environment, it is generally provided as a shell
18779 regular built-in. If it is called in a subshell or separate utility execution environment, such as one
18780 of the following:

```
18781 (getopts abc value "$@")
18782 nohup getopts ...
18783 find . –exec getopts ... \;
```

18784 it does not affect the shell variables in the caller's environment.

18785 Note that shell functions share *OPTIND* with the calling shell even though the positional
18786 parameters are changed. If the calling shell and any of its functions uses *getopts* to parse
18787 arguments, the results are unspecified.

18788 **EXAMPLES**
18789 The following example script parses and displays its arguments:

```
18790 aflag=
18791 bflag=
```

```
18792       while getopts ab: name
18793       do
18794           case $name in
18795           a)    aflag=1;;
18796           b)    bflag=1
18797                 bval="$OPTARG";;
18798           ?)   printf "Usage: %s: [–a] [–b value] args\n" $0
18799                 exit 2;;
18800           esac
18801       done
18802       if [ ! –z "$aflag" ]; then
18803           printf "Option –a specified\n"
18804       fi
18805       if [ ! –z "$bflag" ]; then
18806           printf 'Option –b "%s" specified\n' "$bval"
18807       fi
18808       shift $(($OPTIND – 1))
18809       printf "Remaining arguments are: %s\n" "$*"
```

18810 **RATIONALE**

18811 The *getopts* utility was chosen in preference to the System V *getopt* utility because *getopts* handles
18812 option-arguments containing <blank> characters.

18813 The *OPTARG* variable is not mentioned in the ENVIRONMENT VARIABLES section because it
18814 does not affect the execution of *getopts*; it is one of the few ‘‘output-only’’ variables used by the
18815 standard utilities.

18816 The colon is not allowed as an option character because that is not historical behavior, and it
18817 violates the Utility Syntax Guidelines. The colon is now specified to behave as in the KornShell
18818 version of the *getopts* utility; when used as the first character in the *optstring* operand, it disables
18819 diagnostics concerning missing option-arguments and unexpected option characters. This
18820 replaces the use of the *OPTERR* variable that was specified in an early proposal.

18821 The formats of the diagnostic messages produced by the *getopts* utility and the *getopt*( ) function
18822 are not fully specified because implementations with superior (‘‘friendlier’’) formats objected to
18823 the formats used by some historical implementations. The standard developers considered it
18824 important that the information in the messages used be uniform between *getopts* and *getopt*( ).
18825 Exact duplication of the messages might not be possible, particularly if a utility is built on
18826 another system that has a different *getopt*( ) function, but the messages must have specific
18827 information included so that the program name, invalid option character, and type of error can
18828 be distinguished by a user.

18829 Only a rare application program intercepts a *getopts* standard error message and wants to parse
18830 it. Therefore, implementations are free to choose the most usable messages they can devise. The
18831 following formats are used by many historical implementations:

18832 `"%s: illegal option –– %c\n", <program name>, <option character>`

18833 `"%s: option requires an argument –– %c\n", <program name>, \`
18834 `    <option character>`

18835 Historical shells with built-in versions of *getopt*( ) or *getopts* have used different formats,
18836 frequently not even indicating the option character found in error.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

grep — search a file for a pattern

SYNOPSIS

```
grep [–E| –F][–c| –l| –q][–insvx] –e pattern_list...
    [–f pattern_file]...[file...]

grep [–E| –F][–c| –l| –q][–insvx][–e pattern_list]...
    –f pattern_file...[file...]

grep [–E| –F][–c| –l| –q][–insvx] pattern_list[file...]
```

DESCRIPTION

The *grep* utility shall search the input files, selecting lines matching one or more patterns; the types of patterns are controlled by the options specified. The patterns are specified by the **–e** option, **–f** option, or the *pattern_list* operand. The *pattern_list*'s value shall consist of one or more patterns separated by <newline> characters; the *pattern_file*'s contents shall consist of one or more patterns terminated by <newline> characters. By default, an input line shall be selected if any pattern, treated as an entire basic regular expression (BRE) as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions, matches any part of the line; a null BRE shall match every line. By default, each selected input line shall be written to the standard output.

Regular expression matching shall be based on text lines. Since a <newline> character separates or terminates patterns (see the **–e** and **–f** options below), regular expressions cannot contain a <newline> character. Similarly, since patterns are matched against individual lines of the input, there is no way for a pattern to match a <newline> character found in the input.

OPTIONS

The *grep* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–E Match using extended regular expressions. Treat each pattern specified as an ERE, as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.4, Extended Regular Expressions. If any entire ERE pattern matches some part of an input line, the line shall be matched. A null ERE shall match every line.

–F Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line shall be matched. A null string shall match every line.

–c Write only a count of selected lines to standard output.

–e *pattern_list*
Specify one or more patterns to be used during the search for input. The application shall ensure that patterns in *pattern_list* are separated by a <newline> character. A null pattern can be specified by two adjacent <newline> characters in *pattern_list*. Unless the **–E** or **–F** option is also specified, each pattern shall be treated as a BRE, as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions. Multiple **–e** and **–f** options shall be accepted by the *grep* utility. All of the specified patterns shall be used when matching lines, but the order of evaluation is unspecified.

–f *pattern_file*
Read one or more patterns from the file named by the path name *pattern_file*. Patterns in *pattern_file* shall be terminated by a <newline> character. A null pattern

18891 can be specified by an empty line in *pattern_file*. Unless the –**E** or –**F** option is also
18892 specified, each pattern shall be treated as a BRE, as described in the Base
18893 Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular
18894 Expressions.

18895 –**i** Perform pattern matching in searches without regard to case; see the Base
18896 Definitions volume of IEEE Std. 1003.1-200x, Section 9.2, Regular Expression
18897 General Requirements.

18898 –**l** (The letter ell.) Write only the names of files containing selected lines to standard
18899 output. Path names shall be written once per file searched. If the standard input is
18900 searched, a path name of `"(standard input)"` shall be written, in the POSIX
18901 locale. In other locales, `"standard input"` may be replaced by something more
18902 appropriate in those locales.

18903 –**n** Precede each output line by its relative line number in the file, each file starting at
18904 line 1. The line number counter shall be reset for each file processed.

18905 –**q** Quiet. Do not write anything to the standard output, regardless of matching lines.
18906 Exit with zero status if an input line is selected.

18907 –**s** Suppress the error messages ordinarily written for nonexistent or unreadable files.
18908 Other error messages shall not be suppressed.

18909 –**v** Select lines not matching any of the specified patterns. If the –**v** option is not
18910 specified, selected lines shall be those that match any of the specified patterns.

18911 –**x** Consider only input lines that use all characters in the line to match an entire fixed
18912 string or regular expression to be matching lines.

18913 **OPERANDS**

18914 The following operands shall be supported:

18915 *pattern_list* Specify one or more patterns to be used during the search for input. This operand
18916 shall be treated as if it were specified as –**e** *pattern_list*.

18917 *file* A path name of a file to be searched for the patterns. If no *file* operands are
18918 specified, the standard input shall be used.

18919 **STDIN**

18920 The standard input shall be used only if no *file* operands are specified. See the INPUT FILES
18921 section.

18922 **INPUT FILES**

18923 The input files shall be text files.

18924 **ENVIRONMENT VARIABLES**

18925 The following environment variables shall affect the execution of *grep*:

18926 *LANG* Provide a default value for the internationalization variables that are unset or null.
18927 If *LANG* is unset or null, the corresponding value from the implementation-
18928 defined default locale shall be used. If any of the internationalization variables
18929 contains an invalid setting, the utility shall behave as if none of the variables had
18930 been defined.

18931 *LC_ALL* If set to a non-empty string value, override the values of all the other
18932 internationalization variables.

18933 *LC_COLLATE*
18934 Determine the locale for the behavior of ranges, equivalence classes and multi-

character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If the **–l** option is in effect, and the **–q** option is not, the following shall be written for each file containing at least one selected input line:

`"%s\n", <file>`

Otherwise, if more than one *file* argument appears, and **–q** is not specified, the *grep* utility shall prefix each output line by:

`"%s:", <file>`

The remainder of each output line shall depend on the other options specified:

- If the **–c** option is in effect, the remainder of each output line shall contain:

  `"%d\n", <count>`

- Otherwise, if **–c** is not in effect and the **–n** option is in effect, the following shall be written to standard output:

  `"%d:", <line number>`

- Finally, the following shall be written to standard output:

  `"%s", <selected-line contents>`

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 One or more lines were selected.

1 No lines were selected.

>1 An error occurred.

CONSEQUENCES OF ERRORS

If the **–q** option is specified, the exit status shall be zero if an input line is selected, even if an error was detected. Otherwise, default actions shall be performed.

APPLICATION USAGE

Care should be taken when using characters in *pattern_list* that may also be meaningful to the command interpreter. It is safest to enclose the entire *pattern_list* argument in single quotes:

```
'...'
```

The **–e** *pattern_list* option has the same effect as the *pattern_list* operand, but is useful when *pattern_list* begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple **–e** and **–f** options are accepted and *grep* uses all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)

The **–q** option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if *grep* detected an access or read error on earlier *file* operands).

EXAMPLES

1. To find all uses of the word "Posix" (in any case) in file **text.mm** and write with line numbers:

   ```
   grep –i –n posix text.mm
   ```

2. To find all empty lines in the standard input:

   ```
   grep ^$
   ```

   or:

   ```
   grep –v .
   ```

3. Both of the following commands print all lines containing strings "abc" or "def" or both:

   ```
   grep –E 'abc
   def'
   ```

   ```
   grep –F 'abc
   def'
   ```

4. Both of the following commands print all lines matching exactly "abc" or "def":

   ```
   grep –E '^abc$
   ^def$'
   ```

   ```
   grep –F –x 'abc
   def'
   ```

RATIONALE

This *grep* has been enhanced in an upward-compatible way to provide the exact functionality of the historical *egrep* and *fgrep* commands as well. It was the clear intention of the standard developers to consolidate the three *grep*s into a single command.

The old *egrep* and *fgrep* commands are likely to be supported for many years to come as implementation extensions, allowing historical applications to operate unmodified.

Historical implementations usually silently ignored all but one of multiply-specified **–e** and **–f** options, but were not consistent as to which specification was actually used.

The **–b** option was omitted from the OPTIONS section because block numbers are implementation-defined.

The System V restriction on using – to mean standard input was omitted.

A definition of action taken when given a null BRE or ERE is specified. This is an error condition in some historical implementations.

The **–l** option previously indicated that its use was undefined when no files were explicitly named. This behavior was historical and placed an unnecessary restriction on future implementations. It has been removed.

The historical BSD *grep* **–s** option practice is easily duplicated by redirecting standard output to **/dev/null**. The **–s** option required here is from System V.

The **–x** option, historically available only with *fgrep*, is available here for all of the non-obsolescent versions.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The Open Group corrigenda item U029 / 5 has been applied, correcting the SYNOPSIS.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

19040 **NAME**

19041 hash — remember or report utility locations

19042 **SYNOPSIS**

19043 XSI `hash [utility...]`

19044 `hash –r`

19045

19046 **DESCRIPTION**

19047 The *hash* utility shall affect the way the current shell environment remembers the locations of
19048 utilities found as described in Section 2.9.1.1 (on page 2257). Depending on the arguments
19049 specified, it shall add utility locations to its list of remembered locations or it shall purge the
19050 contents of the list. When no arguments are specified, it shall report on the contents of the list.

19051 Utilities provided as built-ins to the shell shall not be reported by *hash*.

19052 **OPTIONS**

19053 The *hash* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
19054 12.2, Utility Syntax Guidelines.

19055 The following option shall be supported:

19056 **–r** Forget all previously remembered utility locations.

19057 **OPERANDS**

19058 The following operand shall be supported:

19059 *utility* The name of a utility to be searched for and added to the list of remembered
19060 locations. If *utility* contains one or more slashes, the results are unspecified.

19061 **STDIN**

19062 Not used.

19063 **INPUT FILES**

19064 None.

19065 **ENVIRONMENT VARIABLES**

19066 The following environment variables shall affect the execution of *hash*:

19067 *LANG* Provide a default value for the internationalization variables that are unset or null.
19068 If *LANG* is unset or null, the corresponding value from the implementation-
19069 defined default locale shall be used. If any of the internationalization variables
19070 contains an invalid setting, the utility shall behave as if none of the variables had
19071 been defined.

19072 *LC_ALL* If set to a non-empty string value, override the values of all the other
19073 internationalization variables.

19074 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19075 characters (for example, single-byte as opposed to multi-byte characters in
19076 arguments).

19077 *LC_MESSAGES*
19078 Determine the locale that should be used to affect the format and contents of
19079 diagnostic messages written to standard error.

19080 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

19081 *PATH* Determine the location of *utility*, as described in the Base Definitions volume of
19082 IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

19083 **ASYNCHRONOUS EVENTS**
19084 Default.

19085 **STDOUT**
19086 The standard output of *hash* shall be used when no arguments are specified. Its format is
19087 unspecified, but includes the path name of each utility in the list of remembered locations for the
19088 current shell environment. This list shall consist of those utilities named in previous *hash*
19089 invocations that have been invoked, and may contain those invoked and found through the
19090 normal command search process.

19091 **STDERR**
19092 Used only for diagnostic messages.

19093 **OUTPUT FILES**
19094 None.

19095 **EXTENDED DESCRIPTION**
19096 None.

19097 **EXIT STATUS**
19098 The following exit values shall be returned:

19099 0 Successful completion.

19100 >0 An error occurred.

19101 **CONSEQUENCES OF ERRORS**
19102 Default.

19103 **APPLICATION USAGE**
19104 Since *hash* affects the current shell execution environment, it is always provided as a shell
19105 regular built-in. If it is called in a separate utility execution environment, such as one of the
19106 following:

19107 `nohup hash -r`
19108 `find . -type f | xargs hash`

19109 it does not affect the command search process of the caller's environment.

19110 The *hash* utility may be implemented as an alias—for example, *alias* **–t –**, in which case utilities
19111 found through normal command search are not listed by the *hash* command.

19112 The effects of *hash* **–r** can also be achieved portably by resetting the value of *PATH*; in the
19113 simplest form, this can be:

19114 `PATH="$PATH"`

19115 The use of *hash* with *utility* names is unnecessary for most applications, but may provide a
19116 performance improvement on a few implementations; normally, the hashing process is included
19117 by default.

19118 **EXAMPLES**
19119 None.

19120 **RATIONALE**
19121 None.

19122 **FUTURE DIRECTIONS**
19123 None.

19124 **SEE ALSO**

19125 Section 2.9.1.1 (on page 2257)

19126 **CHANGE HISTORY**

19127 First released in Issue 2.

19128 **Issue 4**

19129 Relocated from the *sh* description to reflect its status as a regular built-in utility.

19130 **NAME**

19131 head — copy the first part of files

19132 **SYNOPSIS**

19133 `head [–n number][file...]`

19134 **DESCRIPTION**

19135 The *head* utility shall copy its input files to the standard output, ending the output for each file at
19136 a designated point.

19137 Copying shall end at the point in each input file indicated by the **–n** *number* option. The option-
19138 argument *number* shall be counted in units of lines.

19139 **OPTIONS**

19140 The *head* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
19141 12.2, Utility Syntax Guidelines.

19142 The following option shall be supported:

19143 **–n** *number* The first *number* lines of each input file shall be copied to standard output. The
19144 application shall ensure that the *number* option-argument is a positive decimal
19145 integer.

19146 If no options are specified, *head* shall act as if **–n 10** had been specified.

19147 **OPERANDS**

19148 The following operand shall be supported:

19149 *file* A path name of an input file. If no *file* operands are specified, the standard input
19150 shall be used.

19151 **STDIN**

19152 The standard input shall be used only if no *file* operands are specified. See the INPUT FILES
19153 section.

19154 **INPUT FILES**

19155 Input files shall be text files, but the line length is not restricted to {LINE_MAX} bytes.

19156 **ENVIRONMENT VARIABLES**

19157 The following environment variables shall affect the execution of *head*:

19158 *LANG* Provide a default value for the internationalization variables that are unset or null.
19159 If *LANG* is unset or null, the corresponding value from the implementation-
19160 defined default locale shall be used. If any of the internationalization variables
19161 contains an invalid setting, the utility shall behave as if none of the variables had
19162 been defined.

19163 *LC_ALL* If set to a non-empty string value, override the values of all the other
19164 internationalization variables.

19165 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19166 characters (for example, single-byte as opposed to multi-byte characters in
19167 arguments and input files).

19168 *LC_MESSAGES*

19169 Determine the locale that should be used to affect the format and contents of
19170 diagnostic messages written to standard error.

19171 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

19172 **ASYNCHRONOUS EVENTS**
19173 Default.

19174 **STDOUT**
19175 The standard output shall contain designated portions of the input files.

19176 If multiple *file* operands are specified, *head* shall precede the output for each with the header:

19177 `"\n==> %s <==\n", <pathname>`

19178 except that the first header written shall not include the initial <newline> character.

19179 **STDERR**
19180 Used only for diagnostic messages.

19181 **OUTPUT FILES**
19182 None.

19183 **EXTENDED DESCRIPTION**
19184 None.

19185 **EXIT STATUS**
19186 The following exit values shall be returned:

19187 0 Successful completion.

19188 >0 An error occurred.

19189 **CONSEQUENCES OF ERRORS**
19190 Default.

19191 **APPLICATION USAGE**
19192 The obsolescent *–number* form is withdrawn in this version. Applications should use the **–n**
19193 *number* option.

19194 **EXAMPLES**
19195 To write the first ten lines of all files (except those with a leading period) in the directory:

19196 ```
head *
```

19197 **RATIONALE**
19198 Although it is possible to simulate *head* with *sed* 10q for a single file, the standard developers
19199 decided that the popularity of *head* on historical BSD systems warranted its inclusion alongside
19200 *tail*.

19201 This standard version of *head* follows the Utility Syntax Guidelines. The **–n** option was added to
19202 this new interface so that *head* and *tail* would be more logically related.

19203 There is no **–c** option (as there is in *tail*) because it is not historical practice and because other
19204 utilities in this volume of IEEE Std. 1003.1-200x provide similar functionality.

19205 **FUTURE DIRECTIONS**
19206 None.

19207 **SEE ALSO**
19208 *sed*, *tail*

19209 **CHANGE HISTORY**
19210 First released in Issue 4.
```

Issue 6

The obsolescent **–number** form is withdrawn.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

19214 **NAME**

19215 iconv — codeset conversion

19216 **SYNOPSIS**

19217 `iconv [–cs] –f` *`fromcode`* `–t` *`tocode`* `[`*`file ...`*`]`

19218 `iconv –l`

19219 **DESCRIPTION**

19220 The *iconv* utility shall convert the encoding of characters in *file* from one codeset to another and
19221 write the results to standard output.

19222 When the options indicate that charmap files are used to specify the codesets (see OPTIONS),
19223 the codeset conversion shall be accomplished by performing a logical join on the symbolic
19224 character names in the two charmaps. The implementation need not support the use of charmap
19225 files for codeset conversion unless the POSIX2_LOCALEDEF symbol is defined on the system.

19226 **OPTIONS**

19227 The *iconv* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
19228 12.2, Utility Syntax Guidelines.

19229 The following options shall be supported:

19230 **–c** Omit any invalid characters from the output. When **–c** is not used, the results of
19231 encountering invalid characters in the input stream (either those that are not valid
19232 members of the *fromcode* or those that have no corresponding value in *tocode*) shall
19233 be specified in the system documentation. The presence or absence of **–c** shall not
19234 affect the exit status of *iconv*.

19235 **–f** *fromcode* Identify the codeset of the input file. If the option-argument contains a slash
19236 character, *iconv* shall attempt to use it as the path name of a charmap file, as
19237 defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.4,
19238 Character Set Description File. If the path name does not represent a valid,
19239 readable charmap file, the results are undefined. If the option-argument does not
19240 contain a slash, it shall be considered the name of one of the codeset descriptions
19241 provided by the system, in an unspecified format. The valid values of the option-
19242 argument without a slash are implementation-defined. If this option is omitted, the
19243 codeset of the current locale shall be used.

19244 **–l** Write all supported *fromcode* and *tocode* values to standard output in an unspecified
19245 format.

19246 **–s** Suppress any messages written to standard error concerning invalid characters.
19247 When **–s** is not used, the results of encountering invalid characters in the input
19248 stream (either those that are not valid members of the *fromcode* or those that have
19249 no corresponding value in *tocode*) shall be specified in the system documentation.
19250 The presence or absence of **–s** shall not affect the exit status of *iconv*.

19251 **–t** *tocode* Identify the codeset to be used for the output file. The semantics are equivalent to
19252 the **–f** *fromcode* option.

19253 If either **–f** or **–t** represents a charmap file, but the other does not (or is omitted), or both **–f** and
19254 **–t** are omitted, the results are undefined.

19255 **OPERANDS**

19256 The following operand shall be supported:

19257 *file* A path name of an input file. If no *file* operands are specified, or if a *file* operand is
19258 `'–'`, the standard input shall be used.

19259 **STDIN**

19260 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '–'.

19261 **INPUT FILES**

19262 The input file shall be a text file.

19263 **ENVIRONMENT VARIABLES**

19264 The following environment variables shall affect the execution of *iconv*:

19265 *LANG* Provide a default value for the internationalization variables that are unset or null.
19266 If *LANG* is unset or null, the corresponding value from the implementation-
19267 defined default locale shall be used. If any of the internationalization variables
19268 contains an invalid setting, the utility shall behave as if none of the variables had
19269 been defined.

19270 *LC_ALL* If set to a non-empty string value, override the values of all the other
19271 internationalization variables.

19272 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19273 characters (for example, single-byte as opposed to multi-byte characters in
19274 arguments). During translation of the file, this variable is superseded by the use of
19275 the *fromcode* option-argument.

19276 *LC_MESSAGES*
19277 Determine the locale that should be used to affect the format and contents of
19278 diagnostic messages written to standard error.

19279 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

19280 **ASYNCHRONOUS EVENTS**

19281 Default.

19282 **STDOUT**

19283 When the **–l** option is used, the standard output shall contain all supported *fromcode* and *tocode*
19284 values, written in an unspecified format.

19285 When the **–l** option is not used, the standard output shall contain the sequence of characters
19286 read from the input files, translated to the specified codeset. Nothing else shall be written to the
19287 standard output.

19288 **STDERR**

19289 Used only for diagnostic messages.

19290 **OUTPUT FILES**

19291 None.

19292 **EXTENDED DESCRIPTION**

19293 None.

19294 **EXIT STATUS**

19295 The following exit values shall be returned:

19296 0 Successful completion.

19297 >0 An error occurred.

19298 **CONSEQUENCES OF ERRORS**

19299 Default.

19300 **APPLICATION USAGE**

19301 The user must ensure that both charmap files use the same symbolic names for characters the
19302 two codesets have in common.

19303 **EXAMPLES**

19304 The following example converts the contents of file **mail.x400** from the ISO/IEC 6937:1994
19305 standard codeset to the ISO/IEC 8859-1:1998 standard codeset, and stores the results in file
19306 **mail.local**:

19307 ```
iconv –f IS6937 –t IS8859 mail.x400 > mail.local
```

19308 **RATIONALE**

19309 The *iconv* utility can be used portably only when the user provides two charmap files as option-
19310 arguments. This is because a single charmap provided by the user cannot reliably be joined with
19311 the names in a system-provided character set description. The valid values for *fromcode* and
19312 *tocode* are implementation-defined and do not have to have any relation to the charmap |
19313 mechanisms. As an aid to interactive users, the **–l** option was adopted from the Plan 9 operating
19314 system. It writes information concerning these implementation-defined values. The format is |
19315 unspecified because there are many possible useful formats that could be chosen, such as a
19316 matrix of valid combinations of *fromcode* and *tocode*. The **–l** option is not intended for shell script
19317 usage; portable applications will have to use charmaps.

19318 **FUTURE DIRECTIONS**

19319 None.

19320 **SEE ALSO**

19321 *gencat*

19322 **CHANGE HISTORY**

19323 First released in Issue 3.

19324 **Issue 4**

19325 Format reorganized.

19326 Utility Syntax Guidelines support mandated.

19327 Internationalized environment variable support mandated.

19328 **Issue 6**

19329 This utility has been rewritten to align with the IEEE P1003.2b draft standard. Specifically, the
19330 ability to use charmap files for conversion has been added.
```

NAME

id — return user identity

SYNOPSIS

```
id [user]
id –G[–n] [user]
id –g[–nr] [user]
id –u[–nr] [user]
```

DESCRIPTION

If no *user* operand is provided, the *id* utility shall write the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both shall be written. If multiple groups are supported by the underlying system (see the description of {NGROUPS_MAX} in the System Interfaces volume of IEEE Std. 1003.1-200x), the supplementary group affiliations of the invoking process shall also be written.

If a *user* operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user shall be written. In this case, effective IDs shall be assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, these shall be written in the same manner as the supplementary groups described in the preceding paragraph.

OPTIONS

The *id* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–G Output all different group IDs (effective, real, and supplementary) only, using the format "%u\n". If there is more than one distinct group affiliation, output each such affiliation, using the format " %u", before the <newline> character is output.

–g Output only the effective group ID, using the format "%u\n".

–n Output the name in the format %*s* instead of the numeric ID using the format %*u*.

–r Output the real ID instead of the effective ID.

–u Output only the effective user ID, using the format "%u\n".

OPERANDS

The following operand shall be supported:

user The login name for which information is to be written.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *id*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had

19374 been defined.

19375 *LC_ALL* If set to a non-empty string value, override the values of all the other
19376 internationalization variables.

19377 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19378 characters (for example, single-byte as opposed to multi-byte characters in
19379 arguments).

19380 *LC_MESSAGES*
19381 Determine the locale that should be used to affect the format and contents of
19382 diagnostic messages written to standard error and informative messages written to
19383 standard output.

19384 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

19385 **ASYNCHRONOUS EVENTS**
19386 Default.

19387 **STDOUT**
19388 The following formats shall be used when the *LC_MESSAGES* locale category specifies the
19389 POSIX locale. In other locales, the strings *uid*, *gid*, *euid*, *egid*, and *groups* may be replaced with
19390 more appropriate strings corresponding to the locale.

19391 `"uid=%u(%s) gid=%u(%s)\n", <real user ID>, <user-name>,`
19392 `    <real group ID>, <group-name>`

19393 If the effective and real user IDs do not match, the following shall be inserted immediately
19394 before the `'\n'` character in the previous format:

19395 `" euid=%u(%s)"`

19396 with the following arguments added at the end of the argument list:

19397 `"effective user ID", <effective user-name>`

19398 If the effective and real group IDs do not match, the following shall be inserted directly before
19399 the `'\n'` character in the format string (and after any addition resulting from the effective and
19400 real user IDs not matching):

19401 `" egid=%u(%s)"`

19402 with the following arguments added at the end of the argument list:

19403 `<effective group-ID>, <effective group name>`

19404 If the process has supplementary group affiliations or the selected user is allowed to belong to
19405 multiple groups, the first shall be added directly before the <newline> character in the format
19406 string:

19407 `" groups=%u(%s)"`

19408 with the following arguments added at the end of the argument list:

19409 `<supplementary group ID>, <supplementary group name>`

19410 and the necessary number of the following added after that for any remaining supplementary
19411 group IDs:

19412 `",%u(%s)"`

19413 and the necessary number of the following arguments added at the end of the argument list:

19414 `<supplementary group ID>, <supplementary group name>`

19415 If any of the user ID, group ID, effective user ID, effective group ID, or supplementary/multiple
19416 group IDs cannot be mapped by the system into printable user or group names, the
19417 corresponding (%**s**) and name argument is omitted from the corresponding format string.

19418 When any of the options are specified, the output format shall be as described in the OPTIONS
19419 section.

19420 **STDERR**

19421 Used only for diagnostic messages.

19422 **OUTPUT FILES**

19423 None.

19424 **EXTENDED DESCRIPTION**

19425 None.

19426 **EXIT STATUS**

19427 The following exit values shall be returned:

19428 0 Successful completion.

19429 >0 An error occurred.

19430 **CONSEQUENCES OF ERRORS**

19431 Default.

19432 **APPLICATION USAGE**

19433 Output produced by the **–G** option and by the default case could potentially produce very long
19434 lines on systems that support large numbers of supplementary groups. (On systems with user
19435 and group IDs that are 32-bit integers and with group names with a maximum of 8 bytes per
19436 name, 93 supplementary groups plus distinct effective and real group and user IDs could
19437 theoretically overflow the 2048-byte {LINE_MAX} text file line limit on the default output case.
19438 It would take about 186 supplementary groups to overflow the 2048-byte barrier using *id* **–G**).
19439 This is not expected to be a problem in practice, but in cases where it is a concern, applications
19440 should consider using *fold* **–s** before postprocessing the output of *id*.

19441 **EXAMPLES**

19442 None.

19443 **RATIONALE**

19444 The functionality provided by the 4 BSD *groups* utility can be simulated using:

19445 `id –Gn [ user ]`

19446 The 4 BSD command *groups* was considered, but it was not included because it did not provide
19447 the functionality of the *id* utility of the SVID. Also, it was thought that it would be easier to
19448 modify *id* to provide the additional functionality necessary to systems with multiple groups
19449 than to invent another command.

19450 The options **–u**, **–g**, **–n**, and **–r** were added to ease the use of *id* with shell commands
19451 substitution. Without these options it is necessary to use some preprocessor such as *sed* to select
19452 the desired piece of information. Since output such as that produced by:

19453 `id –u –n`

19454 is frequently wanted, it seemed desirable to add the options.

19455 **FUTURE DIRECTIONS**

19456 None.

19457 **SEE ALSO**

19458 *fold*, *logname*, *who*, the System Interfaces volume of IEEE Std. 1003.1-200x, *getgid*( ), *getgroups*( ),

19460 **CHANGE HISTORY**

19461 First released in Issue 2.

19462 **Issue 4**

19463 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

ipcrm — remove an XSI message queue, semaphore set, or shared memory segment identifier

SYNOPSIS

XSI
```
ipcrm [ –q msgid | –Q msgkey | –s semid | –S semkey |
    –m shmid | –M shmkey ] ...
```

DESCRIPTION

The *ipcrm* utility shall remove zero or more message queues, semaphore sets, or shared memory segments. The interprocess communication facilities to be removed are specified by the options.

Only a user with appropriate privilege shall be allowed to remove an interprocess communication facility that was not created by or owned by the user invoking *ipcrm*.

OPTIONS

The *ipcrm* facility supports the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–q *msgid* Remove the message queue identifier *msgid* from the system and destroy the message queue and data structure associated with it.

–m *shmid* Remove the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

–s *semid* Remove the semaphore identifier *semid* from the system and destroy the set of semaphores and data structure associated with it.

–Q *msgkey* Remove the message queue identifier, created with key *msgkey*, from the system and destroy the message queue and data structure associated with it.

–M *shmkey* Remove the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

–S *semkey* Remove the semaphore identifier, created with key *semkey*, from the system and destroy the set of semaphores and data structure associated with it.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ipcrm*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contain an invalid setting, the utility behaves as if none of the variables had been set.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH
Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
None.

EXAMPLES
None.

RATIONALE
None.

FUTURE DIRECTIONS

CHANGE HISTORY
First released in Issue 5.

NAME

ipcs — report XSI interprocess communication facilities status

SYNOPSIS

XSI
```
ipcs [–qms][–a | –bcopt]
```

DESCRIPTION

The *ipcs* utility shall write information about active interprocess communication facilities.

Without options, information shall be written in short format for message queues, shared memory segments, and semaphores sets that are currently active in the system. Otherwise, the information that is displayed is controlled by the options specified.

OPTIONS

The *ipcs* facility supports the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The *ipcs* utility accepts the following options:

–q Write information about active message queues.

–m Write information about active shared memory segments.

–s Write information about active semaphores sets.

If **–q**, **–m**, or **–s** are specified, only information about those facilities shall be written. If none of these three are specified, information about all three shall be written subject to the following options:

–a Use all print options. (This is a shorthand notation for **–b**, **–c**, **–o**, **–p**, and **–t**.)

–b Write information on maximum allowable size. (Maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores.)

–c Write creator's user name and group name; see below.

–o Write information on outstanding usage. (Number of messages on queue and total number of bytes in messages on queue for message queues, and number of processes attached to shared memory segments.)

–p Write process number information. (Process ID of last process to send a message and process ID of last process to receive a message on message queues, process ID of creating process, and process ID of last process to attach or detach on shared memory segments.)

–t Write time information. (Time of the last control operation that changed the access permissions for all facilities, time of last *msgsnd*( ) and *msgrcv*( ) operations on message queues, time of last *shmat*( ) and *shmdt*( ) operations on shared memory, and time of last *semop*( ) operation on semaphores.)

OPERANDS

None.

STDIN

Not used.

19584 **INPUT FILES**

19585 • The group database

19586 • The user database

19587 **ENVIRONMENT VARIABLES**

19588 The following environment variables shall affect the execution of *ipcs*:

19589 *LANG* Provide a default value for the internationalization variables that are unset or null.
19590 If *LANG* is unset or null, the corresponding value from the implementation-
19591 defined default locale shall be used. If any of the internationalization variables
19592 contain an invalid setting, the utility behaves as if none of the variables had been
19593 set.

19594 *LC_ALL* If set to a non-empty string value, override the values of all the other
19595 internationalization variables.

19596 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19597 characters (for example, single-byte as opposed to multi-byte characters in
19598 arguments).

19599 *LC_MESSAGES*
19600 Determine the locale that should be used to affect the format and contents of
19601 diagnostic messages written to standard error.

19602 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

19603 *TZ* Determine the timezone for the time strings written by *ipcs*.

19604 **ASYNCHRONOUS EVENTS**

19605 Default.

19606 **STDOUT**

19607 An introductory line shall be written with the format:

19608 `"IPC status from %s as of %s\n", <source>, <date>`

19609 where <*source*> indicates the source used to gather the statistics and <*date*> is the information
19610 that would be produced by the *date* command when invoked in the POSIX locale.

19611 The *ipcs* utility then shall create up to three reports depending upon the **–q**, **–m**, and **–s** options.
19612 The first report shall indicate the status of message queues, the second report shall indicate the
19613 status of shared memory segments, and the third report shall indicate the status of semaphore
19614 sets.

19615 If the corresponding facility is not installed or has not been used since the last reboot, then the
19616 report shall be written out in the format:

19617 `"%s facility not in system.\n", <facility>`

19618 where <*facility*> is *Message Queue*, *Shared Memory*, or *Semaphore*, as appropriate. If the facility has
19619 been installed and has been used since the last reboot, column headings separated by one or
19620 more spaces and followed by a <newline> shall be written as indicated below followed by the
19621 facility name written out using the format:

19622 `"%s:\n", <facility>`

19623 where <*facility*> is *Message Queues*, *Shared Memory*, or *Semaphores*, as appropriate. On the second
19624 and third reports the column headings need not be written if the last column headings written
19625 already provide column headings for all information in that report.

The column headings provided in the first column below and the meaning of the information in those columns shall be given in order below; the letters in parentheses indicate the options that shall cause the corresponding column to appear; ''all'' means that the column shall always appear. Each column is separated by one or more <space> characters. Note that these options only determine what information is provided for each report; they do not determine which reports are written.

T (all) Type of facility:

q Message queue.

m Shared memory segment.

s Semaphore.

This field is a single character written using the format %*c*.

ID (all) The identifier for the facility entry. This field shall be written using the format %*d*.

KEY (all) The key used as an argument to *msgget*( ), *semget*( ), or *shmget*( ) to create the facility entry.

Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.

This field shall be written using the format 0*x*%*x*.

MODE (all) The facility access modes and flags. The mode shall consist of 11 characters that are interpreted as follows.

The first character shall be:

S If a process is waiting on a *msgsnd*( ) operation.

– If the above is not true.

The second character shall be:

R If a process is waiting on a *msgrcv*( ) operation.

C or – If the associated shared memory segment is to be cleared when the first attach operation is executed.

– If none of the above is true.

The next nine characters shall be interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the usergroup of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is a minus sign ('–').

The permissions shall be indicated as follows:

r If read permission is granted.

w If write permission is granted.

a If alter permission is granted.

– If the indicated permission is not granted.

19666 The first character following the permissions specifies if there is an alternate
19667 or additional access control method associated with the facility. If there is no
19668 alternate or additional access control method associated with the facility, a
19669 single <space> character shall be written; otherwise, another printable
19670 character is written.

19671 OWNER (all) The user name of the owner of the facility entry. If the user name of the owner
19672 is found in the user database, at least the first eight column positions of the
19673 name shall be written using the format %*s*. Otherwise, the user ID of the
19674 owner shall be written using the format %*d*.

19675 GROUP (all) The group name of the owner of the facility entry. If the group name of the
19676 owner is found in the group database, at least the first eight column positions
19677 of the name shall be written using the format %*s*. Otherwise, the group ID of
19678 the owner shall be written using the format %*d*.

19679 The following nine columns shall be only written out for message queues:

19680 CREATOR (**a**,**c**) The user name of the creator of the facility entry. If the user name of the
19681 creator is found in the user database, at least the first eight column positions
19682 of the name shall be written using the format %*s*. Otherwise, the user ID of
19683 the creator shall be written using the format %*d*.

19684 CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the
19685 creator is found in the group database, at least the first eight column positions
19686 of the name shall be written using the format %*s*. Otherwise, the group ID of
19687 the creator shall be written using the format %*d*.

19688 CBYTES (**a**,**o**) The number of bytes in messages currently outstanding on the associated
19689 message queue. This field shall be written using the format %*d*.

19690 QNUM (**a**,**o**) The number of messages currently outstanding on the associated message
19691 queue. This field shall be written using the format %*d*.

19692 QBYTES (**a**,**b**) The maximum number of bytes allowed in messages outstanding on the
19693 associated message queue. This field shall be written using the format %*d*.

19694 LSPID (**a**,**p**) The process ID of the last process to send a message to the associated queue.
19695 This field shall be written using the format:

19696 `"%d", <`*pid*`>`

19697 where <*pid*> is 0 if no message has been sent to the corresponding message
19698 queue; otherwise, <*pid*> shall be the process ID of the last process to send a
19699 message to the queue.

19700 LRPID (**a**,**p**) The process ID of the last process to receive a message from the associated
19701 queue. This field shall be written using the format:

19702 `"%d", <`*pid*`>`

19703 where <*pid*> is 0 if no message has been received from the corresponding
19704 message queue; otherwise, <*pid*> shall be the process ID of the last process to
19705 receive a message from the queue.

19706 STIME (**a**,**t**) The time the last message was sent to the associated queue. If a message has
19707 been sent to the corresponding message queue, the hour, minute, and second
19708 of the last time a message was sent to the queue shall be written using the
19709 format %*d*:%2.2*d*:%2.2*d*. Otherwise, the format `" no-entry"` shall be written.

RTIME (**a**,**t**) The time the last message was received from the associated queue. If a message has been received from the corresponding message queue, the hour, minute, and second of the last time a message was received from the queue shall be written using the format %*d*:%2.2*d*:%2.2*d*. Otherwise, the format `" no-entry"` shall be written.

The following eight columns shall be only written out for shared memory segments.

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format %*s*. Otherwise, the user ID of the creator shall be written using the format %*d*.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format %*s*. Otherwise, the group ID of the creator shall be written using the format %*d*.

NATTCH (**a**,**o**) The number of processes attached to the associated shared memory segment. This field shall be written using the format %*d*.

SEGSZ (**a**,**b**) The size of the associated shared memory segment. This field shall be written using the format %*d*.

CPID (**a**,**p**) The process ID of the creator of the shared memory entry. This field shall be written using the format %*d*.

LPID (**a**,**p**) The process ID of the last process to attach or detach the shared memory segment. This field shall be written using the format:

`"%d", <`*pid*`>`

where <*pid*> is 0 if no process has attached the corresponding shared memory segment; otherwise, <*pid*> shall be the process ID of the last process to attach or detach the segment.

ATIME (**a**,**t**) The time the last attach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been attached, the hour, minute, and second of the last time the segment was attached shall be written using the format %*d*:%2.2*d*:%2.2*d*. Otherwise, the format `" no-entry"` shall be written.

DTIME (**a**,**t**) The time the last detach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been detached, the hour, minute, and second of the last time the segment was detached shall be written using the format %*d*:%2.2*d*:%2.2*d*. Otherwise, the format `" no-entry"` shall be written.

The following four columns shall be only written out for semaphore sets:

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format %*s* . Otherwise, the user ID of the creator shall be written using the format %*d*.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format %*s*. Otherwise, the group ID of the creator shall be written using the format %*d*.

NSEMS (**a**,**b**) The number of semaphores in the set associated with the semaphore entry. This field shall be written using the format %*d*.

OTIME (**a**,**t**) The time the last semaphore operation on the set associated with the semaphore entry was completed. If a semaphore operation has ever been performed on the corresponding semaphore set, the hour, minute, and second of the last semaphore operation on the semaphore set shall be written using the format %*d*:%2.2*d*:%2.2*d*. Otherwise, the format `" no-entry"` shall be written.

The following column shall be written for all three reports when it is requested:

CTIME (**a**,**t**) The time the associated entry was created or changed. The hour, minute, and second of the time when the associated entry was created shall be written using the format %*d*:%2.2*d*:%2.2*d*.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Things can change while *ipcs* is running; the information it gives is guaranteed to be accurate only when it was retrieved.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5.

Issue 6

The Open Group corrigenda item U020/1 has been applied, correcting the SYNOPSIS.

The Open Group corrigenda items U032/1 and U032/2 have been applied, clarifying the output format.

19797 The Open Group Base Resolution bwg98-004 is applied.

19798 **NAME**

19799 jobs — display status of jobs in the current session

19800 **SYNOPSIS**

19801 UP
```
jobs [–l| –p][job_id...]
```
19802

19803 **DESCRIPTION**

19804 The *jobs* utility shall display the status of jobs that were started in the current shell environment;
19805 see Section 2.13 (on page 2273).

19806 When *jobs* reports the termination status of a job, the shell shall remove its process ID from the
19807 list of those ‘‘known in the current shell execution environment’’; see Section 2.9.3.1 (on page
19808 2259).

19809 **OPTIONS**

19810 The *jobs* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
19811 12.2, Utility Syntax Guidelines.

19812 The following options shall be supported:

19813 **–l** (The letter ell.) Provide more information about each job listed. This information
19814 shall include the job number, current job, process group ID, state, and the
19815 command that formed the job.

19816 **–p** Display only the process IDs for the process group leaders of the selected jobs.

19817 By default, the *jobs* utility shall display the status of all stopped jobs, running background jobs
19818 and all jobs whose status has changed and have not been reported by the shell.

19819 **OPERANDS**

19820 The following operand shall be supported:

19821 *job_id* Specifies the jobs for which the status is to be displayed. If no *job_id* is given, the
19822 status information for all jobs shall be displayed. The format of *job_id* is described
19823 in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.205, Job Control
19824 Job ID.

19825 **STDIN**

19826 Not used.

19827 **INPUT FILES**

19828 None.

19829 **ENVIRONMENT VARIABLES**

19830 The following environment variables shall affect the execution of *jobs*:

19831 *LANG* Provide a default value for the internationalization variables that are unset or null.
19832 If *LANG* is unset or null, the corresponding value from the implementation-
19833 defined default locale shall be used. If any of the internationalization variables
19834 contains an invalid setting, the utility shall behave as if none of the variables had
19835 been defined.

19836 *LC_ALL* If set to a non-empty string value, override the values of all the other
19837 internationalization variables.

19838 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
19839 characters (for example, single-byte as opposed to multi-byte characters in
19840 arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
If the –**p** option is specified, the output shall consist of one line for each process ID:

`"%d\n", <process ID>`

Otherwise, if the –**l** option is not specified, the output shall be a series of lines of the form:

`"[%d] %c %s %s\n", <job-number>, <current>, <state>, <command>`

where the fields shall be as follows:

<*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* %+ or "%%". The character `'–'` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* %–. For other jobs, this field is a <space> character. At most one job can be identified with `'+'` and at most one job can be identified with `'–'`. If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.

<*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<*state*> One of the following strings (in the POSIX locale):

Running Indicates that the job has not been suspended by a signal and has not exited.

Done Indicates that the job completed and returned exit status zero.

Done(*code*) Indicates that the job completed normally and that it exited with the specified non-zero exit status, *code*, expressed as a decimal number.

Stopped Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGTSTP**)
Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGSTOP**)
Indicates that the job was suspended by the SIGSTOP signal.

Stopped (**SIGTTIN**)
Indicates that the job was suspended by the SIGTTIN signal.

Stopped (**SIGTTOU**)
Indicates that the job was suspended by the SIGTTOU signal.

The implementation may substitute the string **Suspended** in place of **Stopped**. If the job was terminated by a signal, the format of <*state*> is unspecified, but it shall be visibly distinct from all of the other <*state*> formats shown here and shall indicate the name or description of the signal causing the termination.

19884 <*command*> The associated command that was given to the shell.

19885 If the **–l** option is specified, a field containing the process group ID shall be inserted before the
19886 <*state*> field. Also, more processes in a process group may be output on separate lines, using
19887 only the process ID and <*command*> fields.

19888 **STDERR**

19889 Used only for diagnostic messages.

19890 **OUTPUT FILES**

19891 None.

19892 **EXTENDED DESCRIPTION**

19893 None.

19894 **EXIT STATUS**

19895 The following exit values shall be returned:

19896 0 Successful completion.

19897 >0 An error occurred.

19898 **CONSEQUENCES OF ERRORS**

19899 Default.

19900 **APPLICATION USAGE**

19901 The **–p** option is the only portable way to find out the process group of a job because different
19902 implementations have different strategies for defining the process group of the job. Usage such
19903 as $(*jobs* –**p**) provides a way of referring to the process group of the job in an implementation-
19904 independent way.

19905 The *jobs* utility does not work as expected when it is operating in its own utility execution
19906 environment because that environment has no applicable jobs to manipulate. See the
19907 APPLICATION USAGE section for *bg* (on page 2422). For this reason, *jobs* is generally
19908 implemented as a shell regular built-in.

19909 **EXAMPLES**

19910 None.

19911 **RATIONALE**

19912 Both "%%" and "%+" are used to refer to the current job. Both forms are of equal validity—the
19913 "%%" mirroring "$$" and "%+" mirroring the output of *jobs*. Both forms reflect historical
19914 practice of the KornShell and the C shell with job control.

19915 The job control features provided by *bg*, *fg*, and *jobs* are based on the KornShell. The standard
19916 developers examined the characteristics of the C shell versions of these utilities and found that
19917 differences exist. Despite widespread use of the C shell, the KornShell versions were selected for
19918 this volume of IEEE Std. 1003.1-200x to maintain a degree of uniformity with the rest of the
19919 KornShell features selected (such as the very popular command line editing features).

19920 The *jobs* utility is not dependent on the job control option, as are the seemingly related *bg* and *fg*
19921 utilities because *jobs* is useful for examining background jobs, regardless of the condition of job
19922 control. When the user has invoked a *set* **+m** command and job control has been turned off, *jobs*
19923 can still be used to examine the background jobs associated with that current session. Similarly,
19924 *kill* can then be used to kill background jobs with *kill*% <*background job number*>.

19925 The output for terminated jobs is left unspecified to accommodate various historical systems.
19926 The following formats have been witnessed:

19927 1. **Killed**(*signal name*)

19928 2. *signal name*

19929 3. *signal name*(**coredump**)

19930 4. *signal description*– **core dumped**

19931 Most users should be able to understand these formats, although it means that applications have
19932 trouble parsing them.

19933 The calculation of job IDs was not described since this would suggest an implementation, which
19934 may impose unnecessary restrictions.

19935 In an early proposal, a –**n** option was included to ‘‘Display the status of jobs that have changed,
19936 exited, or stopped since the last status report’’. It was removed because the shell always writes
19937 any changed status of jobs before each prompt.

19938 **FUTURE DIRECTIONS**

19939 None.

19940 **SEE ALSO**

19941 *bg*, *fg*, *kill*, *wait*

19942 **CHANGE HISTORY**

19943 First released in Issue 4.

19944 **Issue 6**

19945 This utility is now marked as part of the User Portability Utilities option.

19946 The JC shading is removed as job control is mandatory in this issue.

19947 **NAME**

19948 join — relational database operator

19949 **SYNOPSIS**

19950 `join [`–a *file_number* | –v *file_number*`][`–e *string*`][`–o *list*`][`–t *char*`]`
19951 `[`–1 *field*`][`–2 *field*`]` *file1 file2*

19952 **DESCRIPTION**

19953 The *join* utility shall perform an equality join on the files *file1* and *file2*. The joined files shall be
19954 written to the standard output.

19955 The join field is a field in each file on which the files are compared. By default, *join* shall write
19956 one line in the output for each pair of lines in *file1* and *file2* that have identical join fields. The
19957 output line by default shall consist of the join field, then the remaining fields from *file1*, then the
19958 remaining fields from *file2*. This format can be changed by using the **–o** option (see below). The
19959 **–a** option can be used to add unmatched lines to the output. The **–v** option can be used to output
19960 only unmatched lines.

19961 ***Notes to Reviewers***

19962 *This section with side shading will not appear in the final copy. - Ed.*

19963 D1, XCU, ERN 265 proposes to add the following text here: "If the same key appears more than
19964 once in either file, all possible pairwise combinations are output, in unspecified order".

19965 By default, the files *file1* and *file2* should be ordered in the collating sequence of *sort* **–b** on the
19966 fields on which they shall be joined, by default the first in each line. All selected output shall be
19967 written in the same collating sequence.

19968 The default input field separators shall be <blank> characters. In this case, multiple separators
19969 shall count as one field separator, and leading separators shall be ignored. The default output
19970 field separator shall be a <space> character.

19971 The field separator and collating sequence can be changed by using the **–t** option (see below).

19972 If the input files are not in the appropriate collating sequence, the results are unspecified.

19973 **OPTIONS**

19974 The *join* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
19975 12.2, Utility Syntax Guidelines.

19976 The following options shall be supported:

19977 **–a** *file_number*

19978 Produce a line for each unpairable line in file *file_number*, where *file_number* is 1 or
19979 2, in addition to the default output. If both **–a**1 and **–a**2 are specified, all unpairable
19980 lines shall be output.

19981 **–e** *string* Replace empty output fields in the list selected by **–o** with the string *string*.

19982 **–o** *list* Construct the output line to comprise the fields specified in *list*, each element of
19983 which shall have one of the following two forms:

19984 1. *file_number.field*, where *file_number* is a file number and *field* is a decimal
19985 integer field number

19986 2. 0 (zero), representing the join field

19987 The elements of *list* shall be either comma-separated or <blank>-separated, as
19988 specified in Guideline 8 of the Base Definitions volume of IEEE Std. 1003.1-200x,
19989 Section 12.2, Utility Syntax Guidelines. The fields specified by *list* shall be written

for all selected output lines. Fields selected by *list* that do not appear in the input shall be treated as empty output fields. (See the **–e** option.) Only specifically requested fields shall be written. The application shall ensure that *list* is a single command line argument.

–t *char* Use character *char* as a separator, for both input and output. Every appearance of *char* in a line shall be significant. When this option is specified, the collating sequence should be the same as *sort* without the **–b** option.

–v *file_number*
Instead of the default output, produce a line only for each unpairable line in *file_number*, where *file_number* is 1 or 2. If both **–v**1 and **–v**2 are specified, all unpairable lines shall be output.

–1 *field* Join on the *field*th field of file 1. Fields are decimal integers starting with 1.

–2 *field* Join on the *field*th field of file 2. Fields are decimal integers starting with 1.

OPERANDS

The following operands shall be supported:

file1, *file2*
A path name of a file to be joined. If either of the *file1* or *file2* operands is '–', the standard input shall be used in its place.

STDIN

The standard input shall be used only if the *file1* or *file2* operand is '–'. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *join*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale of the collating sequence *join* expects to have been used when the input files were sorted.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

20032 **ASYNCHRONOUS EVENTS**
20033 Default.

20034 **STDOUT**
20035 The *join* utility output shall be a concatenation of selected character fields. When the **–o** option
20036 is not specified, the output shall be:

20037 `"%s%s%s\n", <join field>, <other file1 fields>,`
20038 `<other file2 fields>`

20039 If the join field is not the first field in a file, the *<other file fields>* for that file shall be:

20040 `<fields preceding join field>, <fields following join field>`

20041 When the **–o** option is specified, the output format shall be:

20042 `"%s\n", <concatenation of fields>`

20043 where the concatenation of fields is described by the **–o** option, above.

20044 For either format, each field (except the last) shall be written with its trailing separator character.
20045 If the separator is the default (<blank> characters), a single <space> character shall be written
20046 after each field (except the last).

20047 **STDERR**
20048 Used only for diagnostic messages.

20049 **OUTPUT FILES**
20050 None.

20051 **EXTENDED DESCRIPTION**
20052 None.

20053 **EXIT STATUS**
20054 The following exit values shall be returned:

20055 0 All input files were output successfully.

20056 >0 An error occurred.

20057 **CONSEQUENCES OF ERRORS**
20058 Default.

20059 **APPLICATION USAGE**
20060 Path names consisting of numeric digits or of the form *string.string* should not be specified
20061 directly following the **–o** list.

20062 **EXAMPLES**
20063 The **–o** 0 field essentially selects the union of the join fields. For example, given file **phone**:

```
20064 !Name           Phone Number
20065 Don             +1 123-456-7890
20066 Hal             +1 234-567-8901
20067 Yasushi         +2 345-678-9012
```

20068 and file **fax**:

```
20069 !Name           Fax Number
20070 Don             +1 123-456-7899
20071 Keith           +1 456-789-0122
20072 Yasushi         +2 345-678-9011
```

(where the large expanses of white space are meant to each represent a single <tab> character), the command:

```
join –t "<tab>" –a 1 –a 2 –e '(unknown)' –o 0,1.2,2.2 phone fax
```

would produce:

```
!Name           Phone Number            Fax Number
Don             +1 123-456-7890         +1 123-456-7899
Hal             +1 234-567-8901         (unknown)
Keith           (unknown)               +1 456-789-0122
Yasushi         +2 345-678-9012         +2 345-678-9011
```

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D1, XCU, ERN 265 proposes to add the following example.

The following:

```
fa:
    a x
    a y
    a z
fb:
    a p
    a q
```

would produce:

```
a x p
a x q
a y p
a y q
a z p
a z q
```

RATIONALE

The –**e** option is only effective when used with –**o** because, unless specific fields are identified using –**o**, *join* is not aware of what fields might be empty. The exception to this is the join field, but identifying an empty join field with the –**e** string is not historical practice and some scripts might break if this were changed.

The 0 field in the –**o** list was adopted from the Tenth Edition version of *join* to satisfy international objections that the *join* in the base documents do not support the ''full join'' or ''outer join'' described in relational database literature. Although it has been possible to include a join field in the output (by default, or by field number using –**o**), the join field could not be included for an unpaired line selected by –**a**. The –**o** 0 field essentially selects the union of the join fields.

This sort of outer join was not possible with the *join* commands in the base documents. The –**o** 0 field was chosen because it is an upward-compatible change for applications. An alternative was considered: have the join field represent the union of the fields in the files (where they are identical for matched lines, and one or both are null for unmatched lines). This was not adopted because it would break some historical applications.

The ability to specify *file2* as – is not historical practice; it was added for completeness.

The **–v** option is not historical practice, but was considered necessary because it permitted the writing of *only* those lines that do not match on the join field, as opposed to the **–a** option, which prints both lines that do and do not match. This additional facility is parallel with the **–v** option of *grep*.

Some historical implementations have been encountered where a blank line in one of the input files was considered to be the end of the file; the description in this volume of IEEE Std. 1003.1-200x does not cite this as an allowable case.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The obsolescent **–j** options and the multi-argument **–o** option are withdrawn in this issue.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

20135 **NAME**

20136 kill — terminate or signal processes

20137 **SYNOPSIS**

20138 `kill –s` *`signal_name pid...`*

20139 `kill –l [`*`exit_status`*`]`

20140 **DESCRIPTION**

20141 The *kill* utility shall send a signal to the process or processes specified by each *pid* operand.

20142 For each *pid* operand, the *kill* utility shall perform actions equivalent to the *kill*( ) function
20143 defined in the System Interfaces volume of IEEE Std. 1003.1-200x called with the following
20144 arguments:

20145 • The value of the *pid* operand shall be used as the *pid* argument.

20146 • The *sig* argument is the value specified by the **–s** option, *–signal_number* option, or the
20147 *–signal_name* option, or by SIGTERM, if none of these options is specified.

20148 **OPTIONS**

20149 The *kill* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
20150 12.2, Utility Syntax Guidelines.

20151 The following options shall be supported:

20152 **–l** (The letter ell.) Write all values of *signal_name* supported by the implementation, if
20153 no operand is given. If an *exit_status* operand is given and it is a value of the `'?'`
20154 shell special parameter (see Section 2.5.2 (on page 2241) and *wait* (on page 3254))
20155 corresponding to a process that was terminated by a signal, the *signal_name*
20156 corresponding to the signal that terminated the process shall be written. If an
20157 *exit_status* operand is given and it is the unsigned decimal integer value of a signal
20158 number, the *signal_name* (the symbolic constant name without the **SIG** prefix
20159 defined in the Base Definitions volume of IEEE Std. 1003.1-200x) corresponding to
20160 that signal shall be written. Otherwise, the results are unspecified.

20161 **–s** *signal_name*

20162 Specify the signal to send, using one of the symbolic names defined in the
20163 **<signal.h>** header defined in the Base Definitions volume of IEEE Std. 1003.1-200x,
20164 Chapter 13, Headers. Values of *signal_name* shall be recognized in a case-
20165 independent fashion, without the **SIG** prefix. In addition, the symbolic name 0
20166 shall be recognized, representing the signal value zero. The corresponding signal
20167 shall be sent instead of SIGTERM.

20168 **OPERANDS**

20169 The following operands shall be supported:

20170 *pid* One of the following:

20171 1. A decimal integer specifying a process or process group to be signaled. The
20172 process or processes selected by positive, negative and zero values of the *pid*
20173 operand shall be as described for the *kill*( ) function defined in the System
20174 Interfaces volume of IEEE Std. 1003.1-200x. If process number 0 is specified,
20175 all processes in the current process group are signaled. For the effects of
20176 negative *pid* numbers, see the *kill*( ) function defined in the System Interfaces
20177 volume of IEEE Std. 1003.1-200x. If the first *pid* operand is negative, it should
20178 be preceded by "—" to keep it from being interpreted as an option.

2. A job control job ID (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.205, Job Control Job ID) that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of *kill* in the current shell execution environment; see Section 2.13 (on page 2273).

exit_status A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *kill*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is not specified, the standard output shall not be used.

When the **–l** option is specified, the symbolic name of each signal shall be written in the following format:

`"%s%c", <signal_name>, <separator>`

where the <*signal_name*> is in uppercase, without the **SIG** prefix, and the <*separator*> shall be either a <newline> character or a <space> character. For the last signal written, <*separator*> shall be a <newline> character.

When both the **–l** option and *exit_status* operand are specified, the symbolic name of the corresponding signal shall be written in the following format:

`"%s\n", <signal_name>`

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 At least one matching process was found for each *pid* operand, and the specified signal was successfully processed for at least one matching process.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Process numbers can be found by using *ps*.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not share the shell's understanding of job numbers.

EXAMPLES

Any of the commands:

```
kill –s kill 100 –165
kill –s KILL 100 –165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

The System Interfaces volume of IEEE Std. 1003.1-200x and this volume of IEEE Std. 1003.1-200x do not require specific signal numbers for any *signal_names*. Even the *–signal_number* option provides symbolic (although numeric) names for signals. If a process is terminated by a signal, its exit status indicates the signal that killed it, but the exact values are not specified. The *kill* –**l** option, however, can be used to map decimal signal numbers and exit status values into the name of a signal. The following example reports the status of a terminated job:

```
job
stat=$?
if [ $stat –eq 0 ]
then
    echo job completed successfully.
elif [ $stat –gt 128 ]
then
    echo job terminated by signal SIG$(kill –l $stat).
else
    echo job terminated with error code $stat.
fi
```

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, the ISO / IEC 9945-2: 1993 standard mandates that it always be considered the former. Therefore, to send the default signal to a process group (say 123), an application should use a command similar to one of the following:

```
kill –TERM –123
kill –– –123
```

RATIONALE

The **–l** option originated from the C shell, and is also implemented in the KornShell. The C shell output can consist of multiple output lines because the signal names do not always fit on a single line on some terminal screens. The KornShell output also included the implementation-defined signal numbers and was considered by the standard developers to be too difficult for scripts to parse conveniently. The specified output format is intended not only to accommodate the historical C shell output, but also to permit an entirely vertical or entirely horizontal listing on systems for which this is appropriate.

An early proposal invented the name SIGNULL as a *signal_name* for signal 0 (used by the System Interfaces volume of IEEE Std. 1003.1-200x to test for the existence of a process without sending it a signal). Since the *signal_name* 0 can be used in this case unambiguously, SIGNULL has been removed.

An early proposal also required symbolic *signal_name*s to be recognized with or without the **SIG** prefix. Historical versions of *kill* have not written the **SIG** prefix for the **–l** option and have not recognized the **SIG** prefix on *signal_name*s. Since neither applications portability nor ease-of-use would be improved by requiring this extension, it is no longer required.

This volume of IEEE Std. 1003.1-200x contains no utility that browses for process IDs. Values for *pid* are available via the `'!'` and `'$'` parameters of the shell command language.

The **–s** option was added in response to international interest in providing some form of *kill* that meets the Utility Syntax Guidelines.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not understand how the shell has managed its job numbers.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The obsolescent versions of the SYNOPSIS are withdrawn in this issue.

NAME

lex — generate programs for lexical tasks (**DEVELOPMENT**)

SYNOPSIS

CD

```
lex –c [–t][–n| –v][file ...]
```

DESCRIPTION

The *lex* utility shall generate C programs to be used in lexical processing of character input, and that can be used as an interface to *yacc*. The C programs shall be generated from *lex* source code and conform to the ISO C standard. Usually, the *lex* utility shall write the program it generates to the file **lex.yy.c**; the state of this file is unspecified if *lex* exits with a non-zero exit status. See the EXTENDED DESCRIPTION section for a complete description of the *lex* input language.

OPTIONS

The *lex* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–n Suppress the summary of statistics usually written with the **–v** option. If no table sizes are specified in the *lex* source code and the **–v** option is not specified, then **–n** is implied.

–t Write the resulting program to standard output instead of **lex.yy.c**.

–v Write a summary of *lex* statistics to the standard output. (See the discussion of *lex* table sizes in **Definitions in lex** (on page 2745).) If the **–t** option is specified and **–n** is not specified, this report shall be written to standard error. If table sizes are specified in the *lex* source code, and if the **–n** option is not specified, the **–v** option may be enabled.

OPERANDS

The following operand shall be supported:

file A path name of an input file. If more than one such *file* is specified, all files shall be concatenated to produce a single *lex* program. If no *file* operands are specified, or if a *file* operand is '–', the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, or if a *file* operand is '–'. See INPUT FILES.

INPUT FILES

The input files shall be text files containing *lex* source code, as described in the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

If this variable is not set to the POSIX locale, the results are unspecified.

The following environment variables shall affect the execution of *lex*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **–t** option is specified, the text file of C source code output of *lex* shall be written to standard output.

If the **–t** option is not specified:

- Implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to either the standard output or standard error.
- If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a '%' operator in the *Definitions* section, as long as the **–n** option is not specified.

STDERR

If the **–t** option is specified, implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to the standard error.

If the **–t** option is not specified:

1. Implementation-defined informational, error, and warning messages concerning the contents of *lex* source code input shall be written to either the standard output or standard error.
2. If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a '%' operator in the *Definitions* section, as long as the **–n** option is not specified.

OUTPUT FILES

A text file containing C source code shall be written to **lex.yy.c**, or to the standard output if the **–t** option is present.

EXTENDED DESCRIPTION

Each input file contains *lex* source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.

When **lex.yy.c** is compiled and linked with the *lex* library (using the **–l l** operand with *c99* or *cc*), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.

When an expression is matched, these actions shall occur:

- The input string that was matched is left in *yytext* as a null-terminated string; *yytext* is either an external character array or a pointer to a character string. As explained in **Definitions in lex**, the type can be explicitly selected using the **%array** or **%pointer** declarations, but the default is implementation-defined.
- The external **int** *yyleng* is set to the length of the matching string.
- The expression's corresponding program fragment, or action, is executed.

During pattern matching, *lex* shall search the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first shall be chosen.

The general format of *lex* source shall be:

Definitions
%%
Rules
%%
*User*Subroutines

The first "%%" is required to mark the beginning of the rules (regular expressions and actions); the second "%%" is required only if user subroutines follow.

Any line in the *Definitions* section beginning with a <blank> character shall be assumed to be a C program fragment and shall be copied to the external definition area of the **lex.yy.c** file. Similarly, anything in the *Definitions* section included between delimiter lines containing only "%{" and "%}" shall also be copied unchanged to the external definition area of the **lex.yy.c** file.

Any such input (beginning with a <blank> character or within "%{" and "%}" delimiter lines) appearing at the beginning of the *Rules* section before any rules are specified shall be written to **lex.yy.c** after the declarations of variables for the *yylex* function and before the first line of code in *yylex*. Thus, user variables local to *yylex* can be declared here, as well as application code to execute upon entry to *yylex*.

The action taken by *lex* when encountering any input beginning with a <blank> character or within "%{" and "%}" delimiter lines appearing in the *Rules* section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the *yylex* function.

Definitions in lex

Definitions appear before the first "%%" delimiter. Any line in this section not contained between "%{" and "%}" lines and not beginning with a <blank> character shall be assumed to define a *lex* substitution string. The format of these lines shall be:

name substitute

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* shall replace the string {*name*} when it is used in a rule. The *name* string shall be recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the *Definitions* section, any line beginning with a '%' (percent sign) character and followed by an alphanumeric word beginning with either 's' or 'S' shall define a set of start conditions. Any line beginning with a '%' followed by a word beginning with either 'x' or 'X' shall define a set of exclusive start conditions. When the generated scanner is in a "%s" state, patterns with

20440 no state specified shall be also active; in a "%x" state, such patterns shall not be active. The rest
20441 of the line, after the first word, shall be considered to be one or more <blank> character-
20442 separated names of start conditions. Start condition names shall be constructed in the same way
20443 as definition names. Start conditions can be used to restrict the matching of regular expressions
20444 to one or more states as described in **Regular Expressions in lex** (on page 2747).

20445 Implementations shall accept either of the following two mutually exclusive declarations in the
20446 *Definitions* section:

20447 **%array** Declare the type of *yytext* to be a null-terminated character array.

20448 **%pointer** Declare the type of *yytext* to be a pointer to a null-terminated character string.

20449 The default type of *yytext* is implementation-defined. If an application refers to *yytext* outside of
20450 the scanner source file (that is, via an **extern**), the application shall include the appropriate
20451 **%array** or **%pointer** declaration in the scanner source file.

20452 Implementations shall accept declarations in the *Definitions* section for setting certain internal
20453 table sizes. The declarations are shown in the following table.

20454 **Table 4-9** Table Size Declarations in *lex*

20455

Declaration	Description	Minimum Value
%**p** *n*	Number of positions	2 500
%**n** *n*	Number of states	500
%**a** *n*	Number of transitions	2 000
%**e** *n*	Number of parse tree nodes	1 000
%**k** *n*	Number of packed character classes	1 000
%**o** *n*	Size of the output array	3 000

20462 In the table, *n* represents a positive decimal integer, preceded by one or more <blank>
20463 characters. The exact meaning of these table size numbers is implementation-defined. The
20464 implementation shall document how these numbers affect the *lex* utility and how they are
20465 related to any output that may be generated by the implementation should space limitations be
20466 encountered during the execution of *lex*. It shall be possible to determine from this output which
20467 of the table size values needs to be modified to permit *lex* to successfully generate tables for the
20468 input language. The values in the column Minimum Value represent the lowest values
20469 conforming implementations shall provide.

20470 **Rules in lex**

20471 The rules in *lex* source files are a table in which the left column contains regular expressions and
20472 the right column contains actions (C program fragments) to be executed when the expressions
20473 are recognized.

20474 *ERE action*
20475 *ERE action*
20476 ...

20477 The extended regular expression (*ERE*) portion of a row shall be separated from *action* by one or
20478 more <blank> characters. A regular expression containing <blank> characters shall be
20479 recognized under one of the following conditions:

20480 - The entire expression appears within double-quotes.
20481 - The <blank> characters appear within double-quotes or square brackets.

- Each <blank> character is preceded by a backslash character.

User Subroutines in lex

Anything in the user subroutines section shall be copied to **lex.yy.c** following *yylex*.

Regular Expressions in lex

The *lex* utility shall support the set of extended regular expressions (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.4, Extended Regular Expressions), with the following additions and exceptions to the syntax:

`"..."` Any string enclosed in double-quotes shall represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) shall be recognized. Any backslash-escape sequence shall be terminated by the closing quote. For example, `"\01""1"` represents a single string: the octal value 1 followed by the character `'1'`.

<state>r, *<state1,state2,...>r*
The regular expression *r* shall be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so on; see **Actions in lex** (on page 2749). (As an exception to the typographical conventions of the rest of this volume of IEEE Std. 1003.1-200x, in this case *<state>* does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition shall be recognized as such only at the beginning of a regular expression.

r/*x* The regular expression *r* shall be matched only if it is followed by an occurrence of regular expression *x* (*x* is the instance of trailing context, further defined below). The token returned in *yytext* shall only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the `'$'` (match-end-of-line) operator; *x* cannot include the `'^'` (match-beginning-of-line) operator, nor trailing context, nor the `'$'` operator. That is, only one occurrence of trailing context is allowed in a *lex* regular expression, and the `'^'` operator only can be used at the beginning of such an expression.

{*name*} When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, shall be replaced by the *substitute* value. The *substitute* value shall be treated in the extended regular expression as if it were enclosed in parentheses. No substitution shall occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in the following table shall be recognized.

A literal <newline> character cannot occur within an ERE; the escape sequence `'\n'` can be used to represent a <newline> character. A <newline> character shall not be matched by a period operator.

20522 **Table 4-10** Escape Sequences in *lex*

Escape Sequence	Description	Meaning
`\`*`digits`*	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. If the size of a byte on the system is greater than nine bits, the valid escape sequence used to represent a byte is implementation-defined. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading `'\'` for each byte.
`\x`*`digits`*	A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
`\c`	A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	The character `'c'`, unchanged.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 120, re length limitation for hex, suggests adding a note: "Note: If a hexadecimal escape sequence which is followed by a hexadecimal digit is required, either the character in hex or the following character may be parenthesized using \(and \)."

The order of precedence given to extended regular expressions for *lex* differs from that specified in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.4, Extended Regular Expressions. The order of precedence for *lex* shall be as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context, and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

20567 **Table 4-11** ERE Precedence in *lex*

Extended Regular Expression	Precedence
collation-related bracket symbols	`[= =]  [: :]  [. .]`
escaped characters	`\<special character>`
bracket expression	`[ ]`
quoting	`"..."`
grouping	`( )`
definition	`{name}`
single-character RE duplication	`* + ?`
concatenation	
interval expression	`{m,n}`
alternation	`|`

The ERE anchoring operators '^' and '$') do not appear in the table. With *lex* regular expressions, these operators are restricted in their use: the '^' operator can only be used at the beginning of an entire regular expression, and the '$' operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern "(^abc)|(def$)" is undefined; it can instead be written as two separate rules, one with the regular expression "^abc" and one with "def$", which share a common action via the special '|' action (see below). If the pattern were written "^abc|def$", it would match either "abc" or "def" on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical *lex* implementations. An example of embedded anchoring would be for patterns such as "(^|)foo(|$)" to match "foo" when it exists as a complete word. This functionality can be obtained using existing *lex* features:

```
^foo/[ \n]      |
" foo"/[ \n]    /* Found foo as a separate word. */
```

Note also that '$' is a form of trailing context (it is equivalent to "/\n") and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator '/' can be used as an ordinary character if presented within double-quotes, "/"; preceded by a backslash, "\/"; or within a bracket expression, "[/]". The start-condition '<' and '>' operators shall be special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they shall be treated as ordinary characters.

Actions in lex

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement ';' shall be a valid action; any string in the **lex.yy.c** input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action shall not be valid, and the action *lex* takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
                           program statement }
```

The default action when a string in the input to a **lex.yy.c** program is not matched by any expression shall be to copy the string to the output. Because the default behavior of a program generated by *lex* is to read the input and copy it to the output, a minimal *lex* source program that has just "%%" shall generate a C program that simply copies the input to the output unchanged.

Four special actions shall be available:

```
|   ECHO;   REJECT;   BEGIN
```

| The action '|' means that the action for the next rule is the action for this rule. Unlike the other three actions, '|' cannot be enclosed in braces or be semicolon-terminated; the application shall ensure that it is specified alone, with no other actions.

ECHO; Write the contents of the string *yytext* on the output.

REJECT; Usually only a single expression is matched by a given string in the input. **REJECT** means ''continue to the next expression that matches the current input'', and shall cause whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions "xyz" and "xy" and the input "xyz", usually only the regular expression "xyz" would match. The next attempted match would start after **z.** If the last action in the "xyz" rule is **REJECT**, both this rule and the "xy" rule would be executed. The **REJECT** action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a **goto** to another part of *yylex*. The use of **REJECT** may result in somewhat larger and slower scanners.

BEGIN The action:

```
BEGIN newstate;
```

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the *Definitions* section, the results are unspecified. The initial state is indicated by the digit '0' or the token **INITIAL**.

The functions or macros described below are accessible to user code included in the *lex* input. It is unspecified whether they appear in the C code output of *lex*, or are accessible only through the **–l l** operand to *c99* or *cc* (the *lex* library).

int *yylex*(**void**)
Performs lexical analysis on the input; this is the primary function generated by the *lex* utility. The function shall return zero when the end of input is reached; otherwise, it shall return non-zero values (tokens) determined by the actions that are selected.

int *yymore*(**void**)
When called, indicates that when the next input string is recognized, it is to be appended to the current value of *yytext* rather than replacing it; the value in *yyleng* shall be adjusted accordingly.

int *yyless*(**int** *n*)
Retains *n* initial characters in *yytext*, NUL-terminated, and treats the remaining characters as if they had not been read; the value in *yyleng* shall be adjusted accordingly.

int *input*(**void**)
Returns the next character from the input, or zero on end-of-file. It shall obtain input from the stream pointer *yyin*, although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of *yyin* is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner.

int *unput*(**int** *c*)
Returns the character `'c'` to the input; *yytext* and *yyleng* are undefined until the next expression is matched. The result of using *unput* for more characters than have been input is unspecified.

The following functions appear only in the *lex* library accessible through the **–ll** operand; they can therefore be redefined by a portable application:

int *yywrap*(**void**)
Called by *yylex* at end-of-file; the default *yywrap* always shall return 1. If the application requires *yylex* to continue processing with another source of input, then the application can include a function *yywrap*, which associates another file with the external variable **FILE***yyin and shall return a value of zero.

int *main*(**int** *argc*, **char *** *argv*[ ])
Calls *yylex* to perform lexical analysis, then exits. The user code can contain *main* to perform application-specific operations, calling *yylex* as applicable.

Except for *input*, *unput*, and *main*, all external and static names generated by *lex* shall begin with the prefix **yy** or **YY**.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Portable applications are warned that in the *Rules* section, an *ERE* without an action is not acceptable, but need not be detected as erroneous by *lex*. This may result in compilation or runtime errors.

The purpose of *input* is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The *lex* utility is not fully internationalized in its treatment of regular expressions in the *lex* source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the *lex* source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current *lex* technology. Furthermore, the very nature of the lexical analyzers produced by *lex* must be closely tied to the lexical requirements of the input language being described, which is frequently locale-specific anyway. (For example, writing an analyzer that is used for French text is not automatically useful for processing other languages.)

EXAMPLES

The following is an example of a *lex* program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* Need this for the call to atof() below. */
#include <math.h>
/* Need this for printf(), fopen(), and stdin below. */
#include <stdio.h>
%}
```

```
20704       DIGIT    [0–9]
20705       ID       [a–z][a–z0–9]*
20706       %%
20707       {DIGIT}+ {
20708           printf("An integer: %s (%d)\n", yytext,
20709               atoi(yytext));
20710           }
20711       {DIGIT}+"."{DIGIT}*        {
20712           printf("A float: %s (%g)\n", yytext,
20713               atof(yytext));
20714           }
20715       if|then|begin|end|procedure|function        {
20716           printf("A keyword: %s\n", yytext);
20717           }
20718       {ID}    printf("An identifier: %s\n", yytext);
20719       "+"|"–"|"*"|"/"        printf("An operator: %s\n", yytext);
20720       "{"[^}\n]*"}"    /* Eat up one-line comments. */
20721       [ \t\n]+        /* Eat up white space. */
20722       .  printf("Unrecognized character: %s\n", yytext);
20723       %%
20724       int main(int argc, char *argv[])
20725       {
20726           ++argv, ––argc;  /* Skip over program name. */
20727           if (argc > 0)
20728               yyin = fopen(argv[0], "r");
20729           else
20730               yyin = stdin;
20731           yylex();
20732       }
```

20733 **RATIONALE**

20734 Even though the **–c** option and references to the C language are retained in this description, *lex*
20735 may be generalized to other languages, as was done at one time for EFL, the Extended
20736 FORTRAN Language. Since the *lex* input specification is essentially language-independent,
20737 versions of this utility could be written to produce Ada, Modula-2, or Pascal code, and there are
20738 known historical implementations that do so.

20739 The current description of *lex* bypasses the issue of dealing with internationalized EREs in the *lex*
20740 source code or generated lexical analyzer. If it follows the model used by *awk* (the source code is
20741 assumed to be presented in the POSIX locale, but input and output are in the locale specified by
20742 the environment variables), then the tables in the lexical analyzer produced by *lex* would
20743 interpret EREs specified in the *lex* source in terms of the environment variables specified when
20744 *lex* was executed. The desired effect would be to have the lexical analyzer interpret the EREs
20745 given in the *lex* source according to the environment specified when the lexical analyzer is
20746 executed, but this is not possible with the current *lex* technology.

20747 The description of octal and hexadecimal-digit escape sequences agrees with the ISO C standard
20748 use of escape sequences. See the RATIONALE for *ed* (on page 2546) for a discussion of bytes

larger than 9 bits being represented by octal values. Hexadecimal values can represent larger bytes and multi-byte characters directly, using as many digits as required.

There is no detailed output format specification. The observed behavior of *lex* under four different historical implementations was that none of these implementations consistently reported the line numbers for error and warning messages. Furthermore, there was a desire that *lex* be allowed to output additional diagnostic messages. Leaving message formats unspecified avoids these formatting questions and problems with internationalization.

Although the %*x* specifier for *exclusive* start conditions is not historical practice, it is believed to be a minor change to historical implementations and greatly enhances the usability of *lex* programs since it permits an application to obtain the expected functionality with fewer statements.

The **%array** and **%pointer** declarations were added as a compromise between historical systems. The System V-based *lex* copies the matched text to a *yytext* array. The *flex* program, supported in BSD and GNU systems, uses a pointer. In the latter case, significant performance improvements are available for some scanners. Most historical programs should require no change in porting from one system to another because the string being referenced is null-terminated in both cases. (The method used by *flex* in its case is to null-terminate the token in place by remembering the character that used to come right after the token and replacing it before continuing on to the next scan.) Multi-file programs with external references to *yytext* outside the scanner source file should continue to operate on their historical systems, but would require one of the new declarations to be considered strictly portable.

The description of EREs avoids unnecessary duplication of ERE details because their meanings within a *lex* ERE are the same as that for the ERE in this volume of IEEE Std. 1003.1-200x.

The reason for the undefined condition associated with text beginning with a <blank> or within "%{" and "%}" delimiter lines appearing in the *Rules* section is historical practice. Both the BSD and System V *lex* copy the indented (or enclosed) input in the *Rules* section (except at the beginning) to unreachable areas of the *yylex* function (the code is written directly after a *break* statement). In some cases, the System V *lex* generates an error message or a syntax error, depending on the form of indented input.

The intention in breaking the list of functions into those that may appear in **lex.yy.c** *versus* those that only appear in **libl.a** is that only those functions in **libl.a** can be reliably redefined by a portable application.

The descriptions of standard output and standard error are somewhat complicated because historical *lex* implementations chose to issue diagnostic messages to standard output (unless **–t** was given). This standard allows this behavior, but leaves an opening for the more expected behavior of using standard error for diagnostics. Also, the System V behavior of writing the statistics when any table sizes are given is allowed, while BSD-derived systems can avoid it. The programmer can always precisely obtain the desired results by using either the **–t** or **–n** options.

The OPERANDS section does not mention the use of – as a synonym for standard input; not all historical implementations support such usage for any of the *file* operands.

A description of the *translation table* was deleted from early proposals because of its relatively low usage in historical applications.

The change to the definition of the *input* function that allows buffering of input presents the opportunity for major performance gains in some applications.

The following examples clarify the differences between *lex* regular expressions and regular expressions appearing elsewhere in this volume of IEEE Std. 1003.1-200x. For regular expressions of the form "r/x", the string matching *r* is always returned; confusion may arise

when the beginning of *x* matches the trailing portion of *r*. For example, given the regular expression `"a*b/cc"` and the input `"aaabcc"`, *yytext* would contain the string `"aaab"` on this match. But given the regular expression `"x*/xy"` and the input `"xxxy"`, the token **xxx**, not **xx**, is returned by some implementations because **xxx** matches `"x*"`.

In the rule `"ab*/bc"`, the `"b*"` at the end of *r* extends *r*'s match into the beginning of the trailing context, so the result is unspecified. If this rule were `"ab/bc"`, however, the rule matches the text `"ab"` when it is followed by the text `"bc"`. In this latter case, the matching of *r* cannot extend into the beginning of *x*, so the result is specified.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as part of the C-Language Development Utilities option.

The obsolescent **–c** option is withdrawn in this issue.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

link — call *link*( ) function

SYNOPSIS

XSI
```
link file1 file2
```

DESCRIPTION

The *link* utility shall perform the function call:

```
link(file1, file2);
```

A user may need appropriate privilege to invoke the *link* utility.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

file1 The path name of an existing file.

file2 The path name of the new directory entry to be created.

STDIN

Not used.

INPUT FILES

Not used.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *link*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contain an invalid setting, the utility behaves as if none of the variables had been set.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

20855 **STDERR**

20856 Used only for diagnostic messages.

20857 **OUTPUT FILES**

20858 None.

20859 **EXTENDED DESCRIPTION**

20860 None.

20861 **EXIT STATUS**

20862 The following exit values shall be returned:

20863 0 Successful completion.

20864 >0 An error occurred.

20865 **CONSEQUENCES OF ERRORS**

20866 Default.

20867 **APPLICATION USAGE**

20868 None.

20869 **EXAMPLES**

20870 None.

20871 **RATIONALE**

20872 None.

20873 **FUTURE DIRECTIONS**

20874 None.

20875 **SEE ALSO**

20876 *ln*, *unlink*, the System Interfaces volume of IEEE Std. 1003.1-200x, *link*( )

20877 **CHANGE HISTORY**

20878 First released in Issue 5.

NAME

ln — link files

SYNOPSIS

```
ln [–fs] source_file target_file
ln [–fs] source_file ... target_dir
```

DESCRIPTION

In the first synopsis form, the *ln* utility shall create a new directory entry (link), or if the **–s** option is specified a symbolic link, for the file specified by the *source_file* operand, at the *destination* path specified by the *target_file* operand. This first synopsis form shall be assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error shall result.

In the second synopsis form, the *ln* utility shall create a new directory entry (link), or if the **–s** option is specified a symbolic link, for each file specified by a *source_file* operand, at a *destination* path in the existing directory named by *target_dir*.

If the last operand specifies an existing file of a type not specified by the System Interfaces volume of IEEE Std. 1003.1-200x, the behavior is implementation-defined.

The corresponding *destination* path for each *source_file* shall be the concatenation of the target directory path name, a slash character, and the last path name component of the *source_file*. The second synopsis form shall be assumed when the final operand names an existing directory.

For each *source_file*:

1. If the *destination* path exists:
   a. If the **–f** option is not specified, *ln* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_files*.
   b. Actions shall be performed equivalent to the *unlink*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, called using *destination* as the *path* argument. If this fails for any reason, *ln* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_files*.
2. If the **–s** option is specified, *ln* shall create a symbolic link named by the *destination* path and containing as its path name *source_file*. The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.
3. If *source_file* is a symbolic link, actions shall be performed equivalent to the *link*( ) function using the object that *source_file* references as the *path1* argument and the destination path as the *path2* argument. The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.
4. Actions shall be performed equivalent to the *link*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x using *source_file* as the *path1* argument, and the *destination* path as the *path2* argument.

OPTIONS

The *ln* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–f Force existing *destination* path names to be removed to allow the link.

20922 **–s** Create symbolic links instead of hard links.

20923 **OPERANDS**

20924 The following operands shall be supported:

20925 *source_file* A path name of a file to be linked. If the **–s** option is specified, no restrictions on
20926 the type of file or on its existence shall be made. If the **–s** option is not specified,
20927 whether a directory can be linked is implementation-defined.

20928 *target_file* The path name of the new directory entry to be created.

20929 *target_dir* A path name of an existing directory in which the new directory entries are
20930 created.

20931 **STDIN**

20932 Not used.

20933 **INPUT FILES**

20934 None.

20935 **ENVIRONMENT VARIABLES**

20936 The following environment variables shall affect the execution of *ln*:

20937 *LANG* Provide a default value for the internationalization variables that are unset or null.
20938 If *LANG* is unset or null, the corresponding value from the implementation-
20939 defined default locale shall be used. If any of the internationalization variables
20940 contains an invalid setting, the utility shall behave as if none of the variables had
20941 been defined.

20942 *LC_ALL* If set to a non-empty string value, override the values of all the other
20943 internationalization variables.

20944 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
20945 characters (for example, single-byte as opposed to multi-byte characters in
20946 arguments).

20947 *LC_MESSAGES*

20948 Determine the locale that should be used to affect the format and contents of
20949 diagnostic messages written to standard error.

20950 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

20951 **ASYNCHRONOUS EVENTS**

20952 Default.

20953 **STDOUT**

20954 Not used.

20955 **STDERR**

20956 Used only for diagnostic messages.

20957 **OUTPUT FILES**

20958 None.

20959 **EXTENDED DESCRIPTION**

20960 None.

20961 **EXIT STATUS**

20962 The following exit values shall be returned:

20963 0 All the specified files were linked successfully.

20964 >0 An error occurred.

20965 **CONSEQUENCES OF ERRORS**

20966 Default.

20967 **APPLICATION USAGE**

20968 None.

20969 **EXAMPLES**

20970 None.

20971 **RATIONALE**

20972 Some historic versions of *ln* (including the one specified by the SVID, unlink the destination file,
20973 if it exists, by default. If the mode does not permit writing, these versions prompt for
20974 confirmation before attempting the unlink. In these versions the **–f** option causes *ln* not to
20975 attempt to prompt for confirmation.

20976 This allows *ln* to succeed in creating links when the target file already exists, even if the file itself
20977 is not writable (although the directory must be). Early proposals specified this functionality.

20978 This volume of IEEE Std. 1003.1-200x does not allow the *ln* utility to unlink existing destination
20979 paths by default for the following reasons:

20980 • The *ln* utility has historically been used to provide locking for shell applications, a usage that
20981 is incompatible with *ln* unlinking the destination path by default. There was no
20982 corresponding technical advantage to adding this functionality.

20983 • This functionality gave *ln* the ability to destroy the link structure of files, which changes the
20984 historical behavior of *ln*.

20985 • This functionality is easily replicated with a combination of *rm* and *ln*.

20986 • It is not historical practice in many systems; BSD and BSD-derived systems do not support
20987 this behavior. Unfortunately, whichever behavior is selected can cause scripts written
20988 expecting the other behavior to fail.

20989 • It is preferable that *ln* perform in the same manner as the *link*( ) function, which does not
20990 permit the target to exist already.

20991 This volume of IEEE Std. 1003.1-200x retains the **–f** option to provide support for shell scripts
20992 depending on the SVID semantics. It seems likely that shell scripts would not be written to
20993 handle prompting by *ln* and would therefore have specified the **–f** option.

20994 The **–f** option is an undocumented feature of many historical versions of the *ln* utility, allowing
20995 linking to directories. These versions require modification.

20996 Early proposals of this volume of IEEE Std. 1003.1-200x also required an **–i** option, which
20997 behaved like the **–i** options in *cp* and *mv*, prompting for confirmation before unlinking existing
20998 files. This was not historical practice for the *ln* utility and has been omitted.

20999 **FUTURE DIRECTIONS**

21000 None.

21003 **CHANGE HISTORY**

21004 First released in Issue 2.

21005 **Issue 4**

21006 Aligned with the ISO / IEC 9945-2: 1993 standard.

21007 **Issue 6**

21008 The *ln* utility is updated to include symbolic link processing as defined in the IEEE P1003.2b
21009 draft standard.

NAME

locale — get locale-specific information

SYNOPSIS

```
locale [–a| –m]
locale [–ck] name...
```

DESCRIPTION

The *locale* utility shall write information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a *public locale* is one provided by the implementation that is accessible to the application.

When *locale* is invoked without any arguments, it shall summarize the current locale environment for each locale category as determined by the settings of the environment variables defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 7, Locale.

When invoked with operands, it shall write values that have been assigned to the keywords in the locale categories, as follows:

- Specifying a keyword name shall select the named keyword and the category containing that keyword.
- Specifying a category name shall select the named category and all keywords in that category.

OPTIONS

The *locale* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–a Write information about all available public locales. The available locales shall include **POSIX**, representing the POSIX locale. The manner in which the implementation determines what other locales are available is implementation-defined.

–c Write the names of selected locale categories; see the STDOUT section. The **–c** option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **–k** option.

–k Write the names and values of selected keywords. The implementation may omit values for some keywords; see the OPERANDS section.

–m Write names of available charmaps; see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set.

OPERANDS

The following operand shall be supported:

name The name of a locale category as defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 7, Locale, the name of a keyword in a locale category, or the reserved name **charmap**. The named category or keyword shall be selected for output. If a single *name* represents both a locale category name and a keyword name in the current locale, the results are unspecified. Otherwise, both category and keyword names can be specified as *name* operands, in any sequence. It is implementation-defined whether any keyword values are written for the categories *LC_CTYPE* and *LC_COLLATE*.

21054 **STDIN**

21055 Not used.

21056 **INPUT FILES**

21057 None.

21058 **ENVIRONMENT VARIABLES**

21059 The following environment variables shall affect the execution of *locale*:

21060 *LANG* Provide a default value for the internationalization variables that are unset or null.
21061 If *LANG* is unset or null, the corresponding value from the implementation-
21062 defined default locale shall be used. If any of the internationalization variables
21063 contains an invalid setting, the utility shall behave as if none of the variables had
21064 been defined.

21065 *LC_ALL* If set to a non-empty string value, override the values of all the other
21066 internationalization variables.

21067 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
21068 characters (for example, single-byte as opposed to multi-byte characters in
21069 arguments and input files).

21070 *LC_MESSAGES*
21071 Determine the locale that should be used to affect the format and contents of
21072 diagnostic messages written to standard error.

21073 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

21074 XSI The application shall ensure that the *LANG*, *LC_**, and *NLSPATH* environment variables specify
21075 the current locale environment to be written out; they shall be used if the **–a** option is not
21076 specified.

21077 **ASYNCHRONOUS EVENTS**

21078 Default.

21079 **STDOUT**

21080 If *locale* is invoked without any options or operands, the names and values of the *LANG* and
21081 *LC_** environment variables described in this volume of IEEE Std. 1003.1-200x shall be written to
21082 the standard output, one variable per line, with *LANG* first, and each line using the following
21083 format. Only those variables set in the environment and not overridden by *LC_ALL* shall be
21084 written using this format:

21085 `"%s=%s\n", <variable_name>, <value>`

21086 The names of those *LC_** variables associated with locale categories defined in this volume of
21087 IEEE Std. 1003.1-200x that are not set in the environment or are overridden by *LC_ALL* shall be
21088 written in the following format:

21089 `"%s=\""%s\""\n", <variable_name>, <implied value>`

21090 The <*implied value*> shall be the name of the locale that has been selected for that category by the
21091 implementation, based on the values in *LANG* and *LC_ALL*, as described in the Base Definitions
21092 volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

21093 The <*value*> and <*implied value*> shown above shall be properly quoted for possible later reentry
21094 to the shell. The <*value*> shall not be quoted using double-quotes (so that it can be distinguished
21095 by the user from the <*implied value*> case, which always requires double-quotes).

21096 The *LC_ALL* variable shall be written last, using the first format shown above. If it is not set, it
21097 shall be written as:

21098 `"LC_ALL=\n"`

21099 If any arguments are specified:

21100 1. If the **–a** option is specified, the names of all the public locales shall be written, each in the
21101 following format:

21102 `"%s\n", <locale name>`

21103 2. If the **–c** option is specified, the names of all selected categories shall be written, each in the
21104 following format:

21105 `"%s\n", <category name>`

21106 If keywords are also selected for writing (see following items), the category name output
21107 shall precede the keyword output for that category.

21108 If the **–c** option is not specified, the names of the categories shall not be written; only the
21109 keywords, as selected by the <*name*> operand, shall be written.

21110 3. If the **–k** option is specified, the names and values of selected keywords shall be written. If
21111 a value is non-numeric, it shall be written in the following format:

21112 `"%s=\"%s\"\n", <keyword name>, <keyword value>`

21113 If the keyword was **charmap**, the name of the charmap (if any) that was specified via the
21114 *localedef* **–f** option when the locale was created shall be written, with the word **charmap** as
21115 <*keyword name*>.

21116 If a value is numeric, it shall be written in one of the following formats:

21117 `"%s=%d\n", <keyword name>, <keyword value>`

21118 `"%s=%c%o\n", <keyword name>, <escape character>, <keyword value>`

21119 `"%s=%cx%x\n", <keyword name>, <escape character>, <keyword value>`

21120 where the <*escape character*> is that identified by the **escape_char** keyword in the current
21121 locale; see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3, Locale
21122 Definition.

21123 Compound keyword values (list entries) shall be separated in the output by semicolons.
21124 When included in keyword values, the semicolon, the double-quote, the backslash, and
21125 any control character shall be preceded (escaped) with the escape character.

21126 4. If the **–k** option is not specified, selected keyword values shall be written, each in the
21127 following format:

21128 `"%s\n", <keyword value>`

21129 If the keyword was **charmap**, the name of the charmap (if any) that was specified via the
21130 *localedef* **–f** option when the locale was created shall be written.

21131 5. If the **–m** option is specified, then a list of all available charmaps shall be written, each in
21132 the format:

21133 `"%s\n", <charmap>`

21134 where <*charmap*> is in a format suitable for use as the option-argument to the *localedef* **–f**
21135 option.

21136 **STDERR**

21137 Used only for diagnostic messages.

21138 **OUTPUT FILES**

21139 None.

21140 **EXTENDED DESCRIPTION**

21141 None.

21142 **EXIT STATUS**

21143 The following exit values shall be returned:

21144 0 All the requested information was found and output successfully.

21145 >0 An error occurred.

21146 **CONSEQUENCES OF ERRORS**

21147 Default.

21148 **APPLICATION USAGE**

21149 If the *LANG* environment variable is not set or set to an empty value, or one of the *LC_** |
21150 environment variables is set to an unrecognized value, the actual locales assumed (if any) are |
21151 implementation-defined as described in the Base Definitions volume of IEEE Std. 1003.1-200x, |
21152 Chapter 8, Environment Variables. |

21153 Implementations are not required to write out the actual values for keywords in the categories
21154 *LC_CTYPE* and *LC_COLLATE*; however, they must write out the categories (allowing an
21155 application to determine, for example, which character classes are available).

21156 **EXAMPLES**

21157 In the following examples, the assumption is that locale environment variables are set as
21158 follows:

21159 ```
LANG=locale_x
```
21160 ```
LC_COLLATE=locale_y
```

21161 The command *locale* would result in the following output:

21162 ```
LANG=locale_x
```
21163 ```
LC_CTYPE="locale_x"
```
21164 ```
LC_COLLATE=locale_y
```
21165 ```
LC_TIME="locale_x"
```
21166 ```
LC_NUMERIC="locale_x"
```
21167 ```
LC_MONETARY="locale_x"
```
21168 ```
LC_MESSAGES="locale_x"
```
21169 ```
LC_ALL=
```

21170 The order of presentation of the categories is not specified by this volume of
21171 IEEE Std. 1003.1-200x.

21172 The command:

21173 ```
LC_ALL=POSIX locale –ck decimal_point
```

21174 would produce:

21175 ```
LC_NUMERIC
```
21176 ```
decimal_point="."
```

21177 The following command shows an application of *locale* to determine whether a user-supplied
21178 response is affirmative:
```

```
21179       if printf "%s\n" "$response" | grep –Eq "$(locale yesexpr)"
21180       then
21181           affirmative processing goes here
21182       else
21183           non-affirmative processing goes here
21184       fi
```

21185 **RATIONALE**

21186 The output for categories *LC_CTYPE* and *LC_COLLATE* has been made implementation-defined |
21187 because there is a questionable value in having a shell script receive an entire array of characters. |
21188 It is also difficult to return a logical collation description, short of returning a complete *localedef*
21189 source.

21190 The **–m** option was included to allow applications to query for the existence of charmaps. The
21191 output is a list of the charmaps (implementation-supplied and user-supplied, if any) on the
21192 system.

21193 The **–c** option was included for readability when more than one category is selected (for
21194 example, via more than one keyword name or via a category name). It is valid both with and
21195 without the **–k** option.

21196 The **charmap** keyword, which returns the name of the charmap (if any) that was used when the
21197 current locale was created, was included to allow applications needing the information to
21198 retrieve it.

21199 **FUTURE DIRECTIONS**

21200 None.

21201 **SEE ALSO**

21202 *localedef*, the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3, Locale Definition |

21203 **CHANGE HISTORY**

21204 First released in Issue 4.

21205 **Issue 5**

21206 FUTURE DIRECTIONS section added.

21207 **Issue 6**

21208 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

localedef — define locale environment

SYNOPSIS

```
localedef [–c][–f charmap][–i sourcefile][–u code_set_name] name
```

DESCRIPTION

The *localedef* utility shall convert source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 7, Locale. It is implementation-defined whether users have the capability to create new locales, in addition to those supplied by the implementation. If the symbolic constant POSIX2_LOCALEDEF is defined, the system supports the creation of new locales. On XSI-conformant systems, the symbolic constant POSIX2_LOCALEDEF shall be defined.

The utility shall read source definitions for one or more locale categories belonging to the same locale from the file named in the **–i** option (if specified) or from standard input.

The *name* operand identifies the target locale. The utility shall support the creation of *public*, or generally accessible locales, as well as *private*, or restricted-access locales. Implementations may restrict the capability to create or modify public locales to users with the appropriate privileges.

Each category source definition shall be identified by the corresponding environment variable name and terminated by an **END** *category-name* statement. The following categories shall be supported. In addition, the input may contain source for implementation-defined categories.

LC_CTYPE Defines character classification and case conversion.

LC_COLLATE
: Defines collation rules.

LC_MONETARY
: Defines the format and symbols used in formatting of monetary information.

LC_NUMERIC
: Defines the decimal delimiter, grouping, and grouping symbol for non-monetary numeric editing.

LC_TIME Defines the format and content of date and time information.

LC_MESSAGES
: Defines the format and values of affirmative and negative responses.

OPTIONS

The *localedef* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–c Create permanent output even if warning messages have been issued.

–f *charmap* Specify the path name of a file containing a mapping of character symbols and collating element symbols to actual character encodings. The format of the *charmap* is described under the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.4, Character Set Description File. The application shall ensure that this option is specified if symbolic names (other than collating symbols defined in a **collating-symbol** keyword) are used. If the **–f** option is not present, an implementation-defined character mapping shall be used.

21252 **–i** *inputfile* The path name of a file containing the source definitions. If this option is not
21253 present, source definitions shall be read from standard input. The format of the
21254 *inputfile* is described in the Base Definitions volume of IEEE Std. 1003.1-200x,
21255 Section 7.3, Locale Definition.

21256 **–u** *code_set_name* Specify the name of a codeset used as the target mapping of character symbols
21257 and collating element symbols whose encoding values are defined in terms of the
21258 ISO / IEC 10646-1: 1993 standard position constant values.

21259 **OPERANDS**

21260 The following operand shall be supported:

21261 *name* Identifies the locale; see the Base Definitions volume of IEEE Std. 1003.1-200x,
21262 Chapter 7, Locale for a description of the use of this name. If the name contains one
21263 or more slash characters, *name* shall be interpreted as a path name where the
21264 created locale definitions shall be stored. If *name* does not contain any slash
21265 characters, the interpretation of the name is implementation-defined and the locale
21266 shall be public. This capability may be restricted to users with appropriate
21267 privileges. (As a consequence of specifying one *name*, although several categories
21268 can be processed in one execution, only categories belonging to the same locale can
21269 be processed.)

21270 **STDIN**

21271 Unless the **–i** option is specified, the standard input shall be a text file containing one or more
21272 locale category source definitions, as described in the Base Definitions volume of
21273 IEEE Std. 1003.1-200x, Section 7.3, Locale Definition. When lines are continued using the escape
21274 character mechanism, there is no limit to the length of the accumulated continued line.

21275 **INPUT FILES**

21276 The character set mapping file specified as the *charmap* option-argument is described under the
21277 Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.4, Character Set Description File. If a
21278 locale category source definition contains a **copy** statement, as defined in the Base Definitions
21279 volume of IEEE Std. 1003.1-200x, Chapter 7, Locale, and the **copy** statement names a valid,
21280 existing locale, then *localedef* shall behave as if the source definition had contained a valid
21281 category source definition for the named locale.

21282 **ENVIRONMENT VARIABLES**

21283 The following environment variables shall affect the execution of *localedef*:

21284 *LANG* Provide a default value for the internationalization variables that are unset or null.
21285 If *LANG* is unset or null, the corresponding value from the implementation-
21286 defined default locale shall be used. If any of the internationalization variables
21287 contains an invalid setting, the utility shall behave as if none of the variables had
21288 been defined.

21289 *LC_ALL* If set to a non-empty string value, override the values of all the other
21290 internationalization variables.

21291 *LC_COLLATE*
21292 (This variable has no affect on *localedef*; the POSIX locale is used for this category.)

21293 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
21294 characters (for example, single-byte as opposed to multi-byte characters in
21295 arguments and input files). This variable has no affect on the processing of *localedef*
21296 input data; the POSIX locale is used for this purpose, regardless of the value of this
21297 variable.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The utility shall report all categories successfully processed, in an unspecified format.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
The format of the created output is unspecified. If the *name* operand does not contain a slash, the existence of an output file for the locale is unspecified.

EXTENDED DESCRIPTION
When the **−u** option is used, the *code_set_name* option-argument shall be interpreted as an implementation-defined name of a codeset to which the ISO/IEC 10646-1:1993 standard position constant values shall be converted via an implementation-defined method. Both the ISO/IEC 10646-1:1993 standard position constant values and other formats (decimal, hexadecimal, or octal) shall be valid as encoding values within the *charmap* file. The codeset represented by the implementation-defined name can be any codeset that is supported by the implementation.

When conflicts occur between the *charmap* specification of <*code_set_name*>, <*mb_cur_max*>, or <*mb_cur_min*> and the implementation-defined interpretation of these respective items for the codeset represented by the **−u** option-argument *code_set_name*, the result is unspecified.

When conflicts occur between the *charmap* encoding values specified for symbolic names of characters of the portable character set and the implementation-defined assignment of character encoding values, the result is unspecified.

If a non-printable character in the *charmap* has a width specified that is not **−1**, *localedef* shall generate a warning.

EXIT STATUS
The following exit values shall be returned:

0 No errors occurred and the locales were successfully created.

1 Warnings occurred and the locales were successfully created.

2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.

3 The capability to create new locales is not supported by the implementation.

>3 Warnings or errors occurred and no output was created.

CONSEQUENCES OF ERRORS
If an error is detected, no permanent output shall be created.

If warnings occur, permanent output shall be created if the **−c** option was specified. The following conditions shall cause warning messages to be issued:

- If a symbolic name not found in the *charmap* file is used for the descriptions of the *LC_CTYPE* or *LC_COLLATE* categories (for other categories, this shall be an error condition).

- If the number of operands to the **order** keyword exceeds the {COLL_WEIGHTS_MAX} limit.
- If optional keywords not supported by the implementation are present in the source.
- If a non-printable character has a width specified other than –1.

Other implementation-defined conditions may also cause warnings.

APPLICATION USAGE

The *charmap* definition is optional, and is contained outside the locale definition. This allows both completely self-defined source files, and generic sources (applicable to more than one codeset). To aid portability, all *charmap* definitions must use the same symbolic names for the portable character set. As explained in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.4, Character Set Description File, it is implementation-defined whether or not users or applications can provide additional character set description files. Therefore, the **–f** option might be operable only when an implementation-defined *charmap* is named.

EXAMPLES

None.

RATIONALE

The output produced by the *localedef* utility is implementation-defined. The *name* operand is used to identify the specific locale. (As a consequence, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

FUTURE DIRECTIONS

None.

SEE ALSO

locale, the Base Definitions volume of IEEE Std. 1003.1-200x, Section 7.3, Locale Definition

CHANGE HISTORY

First released in Issue 4.

Issue 6

The **–u** option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

21368 **NAME**

21369 logger — log messages

21370 **SYNOPSIS**

21371 `logger` *`string ...`*

21372 **DESCRIPTION**

21373 The *logger* utility saves a message, in an unspecified manner and format, containing the *string*
21374 operands provided by the user. The messages are expected to be evaluated later by personnel
21375 performing system administration tasks.

21376 It is implementation-defined whether messages written in locales other than the POSIX locale |
21377 are effective.

21378 **OPTIONS**

21379 None.

21380 **OPERANDS**

21381 The following operand shall be supported:

21382 *string* One of the string arguments whose contents are concatenated together, in the
21383 order specified, separated by single <space> characters.

21384 **STDIN**

21385 Not used.

21386 **INPUT FILES**

21387 None.

21388 **ENVIRONMENT VARIABLES**

21389 The following environment variables shall affect the execution of *logger*:

21390 *LANG* Provide a default value for the internationalization variables that are unset or null.
21391 If *LANG* is unset or null, the corresponding value from the implementation- |
21392 defined default locale shall be used. If any of the internationalization variables |
21393 contains an invalid setting, the utility shall behave as if none of the variables had
21394 been defined.

21395 *LC_ALL* If set to a non-empty string value, override the values of all the other
21396 internationalization variables.

21397 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
21398 characters (for example, single-byte as opposed to multi-byte characters in
21399 arguments).

21400 *LC_MESSAGES*
21401 Determine the locale that should be used to affect the format and contents of
21402 diagnostic messages written to standard error. (This means diagnostics from *logger*
21403 to the user or application, not diagnostic messages that the user is sending to the
21404 system administrator.)

21405 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

21406 **ASYNCHRONOUS EVENTS**

21407 Default.

21408 **STDOUT**

21409 Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

Unspecified.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

This utility allows logging of information for later use by a system administrator or programmer in determining why non-interactive utilities have failed. The locations of the saved messages, their format, and retention period are all unspecified. There is no method for a portable application to read messages, once written.

EXAMPLES

A batch application, running non-interactively, tries to read a configuration file and fails; it may attempt to notify the system administrator with:

```
logger myname: unable to read file foo. [timestamp]
```

RATIONALE

The standard developers believed strongly that some method of alerting administrators to errors was necessary. The obvious example is a batch utility, running non-interactively, that is unable to read its configuration files or that is unable to create or write its results file. However, the standard developers did not wish to define the format or delivery mechanisms as they have historically been (and will probably continue to be) very system-specific, as well as involving functionality clearly outside of the scope of this volume of IEEE Std. 1003.1-200x.

The text with *LC_MESSAGES* about diagnostic messages means diagnostics from *logger* to the user or application, not diagnostic messages that the user is sending to the system administrator.

Multiple *string* arguments are allowed, similar to *echo*, for ease-of-use.

Like the utilities *mailx* and *lp*, *logger* is admittedly difficult to test. This was not deemed sufficient justification to exclude these utilities from this volume of IEEE Std. 1003.1-200x. It is also arguable that they are, in fact, testable, but that the tests themselves are not portable.

FUTURE DIRECTIONS

None.

mailx, *write*

CHANGE HISTORY

First released in Issue 4.

21450 **NAME**

21451 logname — return the user's login name

21452 **SYNOPSIS**

21453 `logname`

21454 **DESCRIPTION**

21455 The *logname* utility shall write the user's login name to standard output. The login name shall be
21456 the string that would be returned by the *getlogin*( ) function defined in the System Interfaces
21457 volume of IEEE Std. 1003.1-200x. Under the conditions where the *getlogin*( ) function would fail,
21458 the *logname* utility shall write a diagnostic message to standard error and exit with a non-zero
21459 exit status.

21460 **OPTIONS**

21461 None.

21462 **OPERANDS**

21463 None.

21464 **STDIN**

21465 Not used.

21466 **INPUT FILES**

21467 None.

21468 **ENVIRONMENT VARIABLES**

21469 The following environment variables shall affect the execution of *logname*:

21470 *LANG* Provide a default value for the internationalization variables that are unset or null.
21471 If *LANG* is unset or null, the corresponding value from the implementation-
21472 defined default locale shall be used. If any of the internationalization variables
21473 contains an invalid setting, the utility shall behave as if none of the variables had
21474 been defined.

21475 *LC_ALL* If set to a non-empty string value, override the values of all the other
21476 internationalization variables.

21477 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
21478 characters (for example, single-byte as opposed to multi-byte characters in
21479 arguments).

21480 *LC_MESSAGES*
21481 Determine the locale that should be used to affect the format and contents of
21482 diagnostic messages written to standard error.

21483 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

21484 **ASYNCHRONOUS EVENTS**

21485 Default.

21486 **STDOUT**

21487 The *logname* utility output shall be a single line consisting of the user's login name:

21488 `"%s\n", <login name>`

21489 **STDERR**

21490 Used only for diagnostic messages.

21491 **OUTPUT FILES**

21492 None.

21493 **EXTENDED DESCRIPTION**

21494 None.

21495 **EXIT STATUS**

21496 The following exit values shall be returned:

21497 0 Successful completion.

21498 >0 An error occurred.

21499 **CONSEQUENCES OF ERRORS**

21500 Default.

21501 **APPLICATION USAGE**

21502 The *logname* utility explicitly ignores the *LOGNAME* environment variable because environment
21503 changes could produce erroneous results.

21504 **EXAMPLES**

21505 None.

21506 **RATIONALE**

21507 The **passwd** file is not listed as required because the implementation may have other means of
21508 mapping login names.

21509 **FUTURE DIRECTIONS**

21510 None.

21512 *id*, *who*

21513 **CHANGE HISTORY**

21514 First released in Issue 2.

21515 **Issue 4**

21516 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

lp — send files to a printer

SYNOPSIS

```
lp [–c][–d dest][–n copies][–msw][–o option]... [–t title][file...]
```

DESCRIPTION

The *lp* utility shall copy the input files to an output destination in an unspecified manner. The default output destination should be to a hardcopy device, such as a printer or microfilm recorder, that produces non-volatile, human-readable documents. If such a device is not available to the application, or if the system provides no such device, the *lp* utility shall exit with a non-zero exit status.

The actual writing to the output device may occur some time after the *lp* utility successfully exits. During the portion of the writing that corresponds to each input file, the implementation shall guarantee exclusive access to the device.

The *lp* utility shall associate a unique *request ID* with each request.

Normally, a banner page is produced to separate and identify each print job. This page may be suppressed by implementation-defined conditions, such as an operator command or one of the **–o** *option* values.

OPTIONS

The *lp* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–c Exit only after further access to any of the input files is no longer required. The application can then safely delete or modify the files without affecting the output operation. Normally, files are not copied, but are linked whenever possible. If the **–c** option is not given, then the user should be careful not to remove any of the files before the request has been printed in its entirety. It should also be noted that in the absence of the **–c** option, any changes made to the named files after the request is made but before it is printed are reflected in the printed output. On some systems, **–c** may be on by default.

–d *dest* Specify a string that names the destination (*dest*). If *dest* is a printer, the request shall be printed only on that specific printer. If *dest* is a class of printers, the request shall be printed on the first available printer that is a member of the class. Under certain conditions (printer unavailability, file space limitation, and so on), requests for specific destinations need not be accepted. Destination names vary between systems.

If **–d** is not specified, and neither the *LPDEST* nor *PRINTER* environment variable is set, an unspecified destination is used. The **–d** *dest* option shall take precedence over *LPDEST*, which in turn shall take precedence over *PRINTER*. Results are undefined when *dest* contains a value that is not a valid destination name.

–m Send mail (see *mailx* (on page 2794)) after the files have been printed. By default, no mail is sent upon normal completion of the print request.

–n *copies* Write *copies* number of copies of the files, where *copies* is a positive decimal integer. The methods for producing multiple copies and for arranging the multiple copies when multiple *file* operands are used are unspecified, except that each file shall be output as an integral whole, not interleaved with portions of other files.

−o *option* Specify printer-dependent or class-dependent *option*s. Several such *option*s may be collected by specifying the **−o** option more than once.

−s Suppress messages from *lp*.

−t *title* Write *title* on the banner page of the output.

−w Write a message on the user's terminal after the files have been printed. If the user is not logged in, then mail shall be sent instead.

OPERANDS

The following operand shall be supported:

file A path name of a file to be output. If no *file* operands are specified, or if a *file* operand is '−', the standard input shall be used. If a *file* operand is used, but the **−c** option is not specified, the process performing the writing to the output device may have user and group permissions that differ from that of the process invoking *lp*.

STDIN

The standard input is used only if no *file* operands are specified, or if a *file* operand is '−'. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *lp*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LC_TIME Determine the format and contents of date and time strings displayed in the *lp* banner page, if any.

LPDEST Determine the destination. If the *LPDEST* environment variable is not set, the *PRINTER* environment variable shall be used. The **−d** *dest* option takes precedence over *LPDEST*. Results are undefined when **−d** is not specified and *LPDEST* contains a value that is not a valid destination name.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PRINTER Determine the output device or destination. If the *LPDEST* and *PRINTER* environment variables are not set, an unspecified output device is used. The **−d** *dest* option and the *LPDEST* environment variable shall take precedence over

PRINTER. Results are undefined when **–d** is not specified, *LPDEST* is unset, and *PRINTER* contains a value that is not a valid device or destination name.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *lp* utility shall write a *request ID* to the standard output, unless **–s** is specified. The format of the message is unspecified. The request ID can be used on systems supporting the historical *cancel* and *lpstat* utilities.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 No output device was available, or an error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *pr* and *fold* utilities can be used to achieve reasonable formatting for the implementation's default page size.

A portable application can use one of the *file* operands only with the **–c** option or if the file is publicly readable and guaranteed to be available at the time of printing. This is because the standard gives the implementation the freedom to queue up the request for printing at some later time by a different process that might not be able to access the file.

EXAMPLES

1. To print file *file*:

   ```
   lp –c file
   ```

2. To print multiple files with headers:

   ```
   pr file1 file2 | lp
   ```

RATIONALE

The *lp* utility was designed to be a basic version of a utility that is already available in many historical implementations. The standard developers considered that it should be implementable simply as:

```
cat "$@" > /dev/lp
```

after appropriate processing of options, if that is how the implementation chose to do it and if exclusive access could be granted (so that two users did not write to the device simultaneously). Although in the future the standard developers may add other options to this utility, it should always be able to execute with no options or operands and send the standard input to an unspecified output device.

This volume of IEEE Std. 1003.1-200x makes no representations concerning the format of the printed output, except that it must be ‘‘human-readable’’ and ‘‘non-volatile’’. Thus, writing by default to a disk or tape drive or a display terminal would not qualify. (Such destinations are not prohibited when **−d** *dest*, *LPDEST*, or *PRINTER* are used, however.)

This volume of IEEE Std. 1003.1-200x is worded such that a ‘‘print job’’ consisting of multiple input files, possibly in multiple copies, is guaranteed to print so that any one file is not intermixed with another, but there is no statement that all the files or copies have to print out together.

The **−c** option may imply a spooling operation, but this is not required. The utility can be implemented to wait until the printer is ready and then wait until it is finished. Because of that, there is no attempt to define a queuing mechanism (priorities, classes of output, and so on).

On some historical systems, the request ID reported on the STDOUT can be used to later cancel or find the status of a request using utilities not defined in this volume of IEEE Std. 1003.1-200x.

Although the historical System V *lp* and BSD *lpr* utilities have provided similar functionality, they used different names for the environment variable specifying the destination printer. Since the name of the utility here is *lp*, *LPDEST* (used by the System V *lp* utility) was given precedence over *PRINTER* (used by the BSD *lpr* utility). Since environments of users frequently contain one or the other environment variable, the *lp* utility is required to recognize both. If this was not done, many applications would send output to unexpected output devices when users moved from system to system.

Some have commented that *lp* has far too little functionality to make it worthwhile. Requests have proposed additional options or operands or both that added functionality. The requests included:

- Wording *requiring* the output to be ‘‘hardcopy’’
- A requirement for multiple printers
- Options for supporting various page-description languages

Given that a compliant system is not required to even have a printer, placing further restrictions upon the behavior of the printer is not useful. Since hardcopy format is so application-dependent, it is difficult, if not impossible, to select a reasonable subset of functionality that should be required on all compliant systems.

The term ‘‘unspecified’’ is used in this section in lieu of ‘‘implementation-defined’’ as most known implementations would not be able to make definitive statements in their conformance documents: the existence and usage of printers is very dependent on how the system administrator configures each individual system.

Since the default destination, device type, queuing mechanisms, and acceptable forms of input are all unspecified, usage guidelines for what a portable application can do are as follows:

- Use the command in a pipeline, or with **−c**, so that there are no permission problems and the files can be safely deleted or modified.
- Limit output to text files of reasonable line lengths and printable characters and include no device-specific formatting information, such as a page description language. The meaning of ‘‘reasonable’’ in this context can only be answered as a quality-of-implementation issue, but it should be apparent from historical usage patterns in the industry and the locale. The *pr* and *fold* utilities can be used to achieve reasonable formatting for the default page size of the implementation.

Alternatively, the application can arrange its installation in such a way that it requires the system administrator or operator to provide the appropriate information on *lp* options and environment variable values.

At a minimum, having this utility in this volume of IEEE Std. 1003.1-200x tells the industry that portable applications require a means to print output and provides at least a command name and *LPDEST* routing mechanism that can be used for discussions between vendors, application writers, and users. The use of ‘‘should’’ in the DESCRIPTION of *lp* clearly shows the intent of the standard developers, even if they cannot mandate that all systems (such as laptops) have printers.

This volume of IEEE Std. 1003.1-200x does not specify what the ownership of the process performing the writing to the output device may be. If **–c** is not used, it is unspecified whether the process performing the writing to the output device has permission to read *file* if there are any restrictions in place on who may read *file* until after it is printed. Also, if **–c** is not used, the results of deleting *file* before it is printed are unspecified.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the requirement to associate a unique request ID, and the normal generation of a banner page is added.
- In the OPTIONS section:
  - The **–d** *dest* description is expanded, but references to *lpstat* are removed.
  - The **–m**, **–o**, **–s**, **–t**, and **–w** options are added.
- In the ENVIRONMENT VARIABLES section, *LC_TIME* may now affect the execution.
- The STDOUT section is added.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

ls — list directory contents

SYNOPSIS

XSI `ls [–CFRacdilqrtu1][–H | –L ][–fgmnopsx][`*file*`...]`

DESCRIPTION

For each operand that names a file of a type other than directory or symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. For each operand that names a file of type directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. If one of the **–d**, **–F**, or **–l** options are specified, and one of the **–H** or **–L** options are not specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. If none of the **–d**, **–F**, or **–l** options are specified, or the **–H** or **–L** options are specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information.

If no operands are specified, *ls* shall write the contents of the current directory. If more than one operand is specified, *ls* shall write non-directory operands first; it shall sort directory and non-directory operands separately according to the collating sequence in the current locale.

The *ls* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *ls* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *ls* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–C Write multi-text-column output with entries sorted down the columns, according to the collating sequence. The number of text columns and the column separator characters are unspecified, but should be adapted to the nature of the output device.

–F Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Write a slash (`'/'`) immediately after each path name that is a directory, an asterisk (`'*'`) after each that is executable, a vertical bar (`'|'`) after each that is a FIFO, and an at sign (`'@'`) after each that is a symbolic link. For other file types, other symbols may be written.

–H If a symbolic link referencing a file of type directory is specified on the command line, *ls* shall evaluate the file information and file type to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link.

–L Evaluate the file information and file type for all symbolic links (whether named on the command line or encountered in a file hierarchy) to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link. When **–L** is used with **–l**, write the contents of symbolic links in the long format (see the STDOUT section).

–R Recursively list subdirectories encountered.

–a Write out all directory entries, including those whose names begin with a period (`'.'`). Entries beginning with a period shall not be written out unless explicitly

referenced, the –**a** option is supplied, or an implementation-defined condition shall cause them to be written.

–**c** Use time of last modification of the file status information (see **<sys/stat.h>** in the System Interfaces volume of IEEE Std. 1003.1-200x) instead of last modification of the file itself for sorting (–**t**) or writing (–**l**).

–**d** Do not follow symbolic links named as operands unless the –**H** or –**L** options are specified. Do not treat directories differently than other types of files. The use of –**d** with –**R** produces unspecified results.

XSI –**f** Force each argument to be interpreted as a directory and list the name found in each slot. This option shall turn off –**l**, –**t**, –**s**, and –**r**, and shall turn on –**a**; the order is the order in which entries appear in the directory.

XSI –**g** The same as –**l**, except that the owner shall not be written.

–**i** For each file, write the file's file serial number (see *stat*( ) in the System Interfaces volume of IEEE Std. 1003.1-200x).

–**l** (The letter ell.) Do not follow symbolic links named as operands unless the –**H** or –**L** options are specified. Write out in long format (see the STDOUT section). When –**l** (ell) is specified, –1 (one) shall be assumed.

XSI –**m** Stream output format; list files across the page, separated by commas.

XSI –**n** The same as –**l**, except that the owner's UID and GID numbers are written, rather than the associated character strings.

XSI –**o** The same as –**l**, except that the group is not written.

XSI –**p** Write a slash (`'/'`) after each file name if that file is a directory.

–**q** Force each instance of non-printable file name characters and <tab> characters to be written as the question-mark (`'?'`) character. Implementations may provide this option by default if the output is to a terminal device.

–**r** Reverse the order of the sort to get reverse collating sequence or oldest first.

XSI –**s** Indicate the total number of file system blocks consumed by each file displayed. The block size is implementation-defined.

–**t** Sort by time modified (most recently modified first) before sorting the operands by the collating sequence.

–**u** Use time of last access (see **<sys/stat.h>** in the System Interfaces volume of IEEE Std. 1003.1-200x) instead of last modification of the file for sorting (–**t**) or writing (–**l**).

XSI –**x** The same as –**C**, except that the multi-text-column output is produced with entries sorted across, rather than down, the columns.

–**1** (The numeric digit one.) Force output to be one entry per line.

Specifying more than one of the options in the following mutually exclusive pairs shall not be considered an error: –**C** and –**l** (ell), –**m** and –**l** (ell), –**x** and –**l** (ell), –**C** and –**1** (one), –**H** and –**L**, –**c** and –**u**. The last option specified in each pair shall determine the output format.

21810 **OPERANDS**

21811 The following operand shall be supported:

21812 *file* A path name of a file to be written. If the file specified is not found, a diagnostic
21813 message shall be output on standard error.

21814 **STDIN**

21815 Not used.

21816 **INPUT FILES**

21817 None.

21818 **ENVIRONMENT VARIABLES**

21819 The following environment variables shall affect the execution of *ls*:

21820 *COLUMNS* Determine the user's preferred column position width for writing multiple text-
21821 column output. If this variable contains a string representing a decimal integer, the
21822 *ls* utility shall calculate how many path name text columns to write (see **–C**) based
21823 on the width provided. If *COLUMNS* is not set or invalid, an implementation-
21824 defined number of column positions shall be assumed, based on the
21825 implementation's knowledge of the output device. The column width chosen to
21826 write the names of files in any given directory shall be constant. File names shall
21827 not be truncated to fit into the multiple text-column output.

21828 *LANG* Provide a default value for the internationalization variables that are unset or null.
21829 If *LANG* is unset or null, the corresponding value from the implementation-
21830 defined default locale shall be used. If any of the internationalization variables
21831 contains an invalid setting, the utility shall behave as if none of the variables had
21832 been defined.

21833 *LC_ALL* If set to a non-empty string value, override the values of all the other
21834 internationalization variables.

21835 *LC_COLLATE*
21836 Determine the locale for character collation information in determining the path
21837 name collation sequence.

21838 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
21839 characters (for example, single-byte as opposed to multi-byte characters in
21840 arguments) and which characters are defined as printable (character class **print**).

21841 *LC_MESSAGES*
21842 Determine the locale that should be used to affect the format and contents of
21843 diagnostic messages written to standard error.

21844 *LC_TIME* Determine the format and contents for date and time strings written by *ls*.

21845 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

21846 *TZ* Determine the timezone for date and time strings written by *ls*.

21847 **ASYNCHRONOUS EVENTS**

21848 Default.

21849 **STDOUT**

21850 The default format shall be to list one entry per line to standard output; the exceptions are to
21851 XSI terminals or when one of the **–C**, **–m**, or **–x** options is specified. If the output is to a terminal, the
21852 format is implementation-defined.

21853 XSI When –**m** is specified, the format used shall be:

21854 `"%s, %s, ...\n", <filename1>, <filename2>`

21855 where the largest number of file names shall be written without exceeding the length of the line.

21856 If the –**i** option is specified, the file's file serial number (see **<sys/stat.h>** in the System Interfaces
21857 volume of IEEE Std. 1003.1-200x) shall be written in the following format before any other
21858 output for the corresponding entry:

21859 `%u ", <file serial number>`

21860 If the –**l** option is specified without –**L**, the following information shall be written:

```
21861 "%s %u %s %s %u %s %s\n", <file mode>, <number of links>,
21862     <owner name>, <group name>, <number of bytes in the file>,
21863     <date and time>, <pathname>
```

21864 If the file is a symbolic link, this information shall be about the link itself and the <*pathname*>
21865 field shall be of the form:

21866 `"%s –> %s", <pathname of link>, <contents of link>`

21867 If both –**l** and –**L** are specified, the following information shall be written:

```
21868 "%s %u %s %s %u %s %s0, <file mode>, <number of links>,
21869     <owner name>, <group name>, <number of bytes in the file>,
21870     <date and time>, <pathname of link>
```

21871 where all fields except <*pathname of link*> shall be for the file resolved from the symbolic link.

21872 XSI The –**g**, –**n**, and –**o** options use the same format as –**l**, but with omitted items and their
21873 associated <blank> characters. See the OPTIONS section.

21874 XSI In both the preceding –**l** forms, If <*owner name*> or <*group name*> cannot be determined, or if –**n**
21875 is given,they shall be replaced with their associated numeric values using the format %*u*.

21876 The <*date and time*>, field shall contain the appropriate date and timestamp of when the file was
21877 last modified. In the POSIX locale, the field shall be the equivalent of the output of the following
21878 *date* command:

21879 `date "+%b %e %H:%M"`

21880 if the file has been modified in the last six months, or:

21881 `date "+%b %e %Y"`

21882 (where two <space> characters are used between %*e* and %*Y*) if the file has not been modified in
21883 the last six months or if the modification date is in the future, except that, in both cases, the final
21884 <newline> character produced by *date* shall not be included and the output shall be as if the *date*
21885 command were executed at the time of the last modification date of the file rather than the
21886 current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format
21887 and order of presentation of this field may be used.

21888 If the file is a character special or block special file, the size of the file may be replaced with
21889 implementation-defined information associated with the device in question.

21890 If the path name was specified as a *file* operand, it shall be written as specified.

21891 XSI The file mode written under the –**l**, –**g**, –**n**, and –**o** options shall consist of the following format:

```
21892 "%c%s%s%s%c", <entry type>, <owner permissions>,
21893     <group permissions>, <other permissions>,
```

21894 `<optional alternate access method flag>`

21895 The *<optional alternate access method flag>* shall be a single <space> character if there is no
21896 alternate or additional access control method associated with the file; otherwise, a printable
21897 character shall be used.

21898 The *<entry type>* character shall describe the type of file, as follows:

21899 d Directory.

21900 b Block special file.

21901 c Character special file.

21902 l (ell) Symbolic link.

21903 p FIFO.

21904 – Regular file.

21905 Implementations may add other characters to this list to represent other implementation-defined
21906 file types.

21907 The next three fields shall be three characters each:

21908 *<owner permissions>*
21909 Permissions for the file owner class (see the Base Definitions volume of
21910 IEEE Std. 1003.1-200x, Section 4.1, File Access Permissions).

21911 *<group permissions>*
21912 Permissions for the file group class.

21913 *<other permissions>*
21914 Permissions for the file other class.

21915 Each field shall have three character positions:

21916 1. If `'r'`, the file is readable; if `'–'`, the file is not readable.

21917 2. If `'w'`, the file is writable; if `'–'`, the file is not writable.

21918 3. The first of the following that applies:

21919 S If in *<owner permissions>*, the file is not executable and set-user-ID mode is set. If in
21920 *<group permissions>*, the file is not executable and set-group-ID mode is set.

21921 s If in *<owner permissions>*, the file is executable and set-user-ID mode is set. If in
21922 *<group permissions>*, the file is executable and set-group-ID mode is set.

21923 x The file is executable or the directory is searchable.

21924 – None of the attributes of `'S'`, `'s'`, or `'x'` applies.

21925 Implementations may add other characters to this list for the third character position. Such
21926 additions shall, however, be written in lowercase if the file is executable or searchable, and
21927 in uppercase if it is not.

21928 XSI If any of the **–l**, **–g**, **–n**, **–o**, or **–s** options is specified, each list of files within the directory shall be
21929 preceded by a status line indicating the number of file system blocks occupied by files in the
21930 directory in 512-byte units, rounded up to the next integral number of units, if necessary. In the
21931 POSIX locale, the format shall be:

21932 `"total %u\n", <number of units in the directory>`

If more than one directory, or a combination of non-directory files and directories are written, either as a result of specifying multiple operands, or the **–R** option, each list of files within a directory shall be preceded by:

`"\n%s:\n", <directory name>`

If this string is the first thing to be written, the first <newline> character shall not be written. This output shall precede the number of units in the directory.

XSI If the **–s** option is given, each file shall be written with the number of blocks used by the file. Along with **–C**, **–1**, **–m**, or **–x**, the number and a <space> character shall precede the file name; with **–g**, **–l**, **–n**, or **–o**, they shall precede each line describing a file.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many implementations use the equal sign (`'='`) and the at sign (`'@'`) to denote sockets bound to the file system and symbolic links, respectively, for the **–F** option. Similarly, many historical implementations use the `'s'` character and the `'l'` character to denote sockets and symbolic links, respectively, as the entry type characters for the **–l** option.

It is difficult for an application to use every part of the file modes field of *ls* **–l** in a portable manner. Certain file types and executable bits are not guaranteed to be exactly as shown, as implementations may have extensions. Applications can use this field to pass directly to a user printout or prompt, but actions based on its contents should generally be deferred, instead, to the *test* utility.

The output of *ls* (with the **–l** and related options) contains information that logically could be used by utilities such as *chmod* and *touch* to restore files to a known state. However, this information is presented in a format that cannot be used directly by those utilities or be easily translated into a format that can be used. A character has been added to the end of the permissions string so that applications at least have an indication that they may be working in an area they do not understand instead of assuming that they can translate the permissions string into something that can be used. Future issues or related documents may define one or more specific characters to be used based on different standard additional or alternative access control mechanisms.

As with many of the utilities that deal with file names, the output of *ls* for multiple files or in one of the long listing formats must be used carefully on systems where file names can contain embedded white space. Systems and system administrators should institute policies and user training to limit the use of such file names.

The number of disk blocks occupied by the file that it reports varies depending on underlying file system type, block size units reported, and the method of calculating the number of blocks. On some file system types, the number is the actual number of blocks occupied by the file (counting indirect blocks and ignoring holes in the file); on others it is calculated based on the file size (usually making an allowance for indirect blocks, but ignoring holes).

EXAMPLES

An example of a small directory tree being fully listed with *ls* –**laRF a** in the POSIX locale:

```
total 11
drwxr-xr-x   3 hlj      prog          64 Jul  4 12:07 ./
drwxrwxrwx   4 hlj      prog        3264 Jul  4 12:09 ../
drwxr-xr-x   2 hlj      prog          48 Jul  4 12:07 b/
-rwxr--r--   1 hlj      prog         572 Jul  4 12:07 foo*

a/b:
total 4
drwxr-xr-x   2 hlj      prog          48 Jul  4 12:07 ./
drwxr-xr-x   3 hlj      prog          64 Jul  4 12:07 ../
-rw-r--r--   1 hlj      prog         700 Jul  4 12:07 bar
```

RATIONALE

Some historical implementations of the *ls* utility show all entries in a directory except dot and dot-dot when a superuser invokes *ls* without specifying the –**a** option. When ‘‘normal’’ users invoke *ls* without specifying –**a**, they should not see information about any files with names beginning with period unless they were named as *file* operands.

Implementations are expected to traverse arbitrary depths when processing the –**R** option. The only limitation on depth should be based on running out of physical storage for keeping track of untraversed directories.

The –**1** (one) option is currently found in BSD and BSD-derived implementations only. It is required in this volume of IEEE Std. 1003.1-200x so that portable applications might ensure that output is one entry per line, even if the output is to a terminal.

Generally, this volume of IEEE Std. 1003.1-200x is silent about what happens when options are given multiple times. In the cases of –**C**, –**l**, and –**1**, however, it does specify the results of these overlapping options. Since *ls* is one of the most aliased commands, it is important that the implementation perform intuitively. For example, if the alias were:

```
alias ls="ls –C"
```

and the user typed *ls* –**1**, single-text-column output should result, not an error.

The BSD *ls* provides a –**A** option (like –**a**, but dot and dot-dot are not written out). The small difference from –**a** did not seem important enough to require both.

Implementations are allowed to make –**q** the default for terminals to prevent trojan horse attacks on terminals with special escape sequences. This is not required because:

- Some control characters may be useful on some terminals; for example, a system might write them as `"\001"` or `"^A"`.
- Special behavior for terminals is not relevant to application portability.

An early proposal specified that the optional alternate access method flag had to be `'+'` if there was an alternate access method used on the file or <space> if there was not. This was changed to be <space> if there is not and a single printable character if there is. This was done for three reasons:

22022 1. There are historical implementations using characters other than '+'.

22023 2. There are implementations that vary this character used in that position to distinguish
22024 between various alternate access methods in use.

22025 3. The standard developers did not want to preclude futures specifications that might need a
22026 way to specify more than one alternate access method.

22027 Nonetheless, implementations providing a single alternate access method are encouraged to use
22028 '+'.

22029 In an early proposal, the units used to specify the number of blocks occupied by files in a
22030 directory in an *ls* **–l** listing was implementation-defined. This was because BSD systems have
22031 historically used 1 024-byte units and System V systems have historically used 512-byte units. It
22032 was pointed out by BSD developers that their system has used 512-byte units in some places and
22033 1 024-byte units in other places. (System V has consistently used 512.) Therefore, this volume of
22034 IEEE Std. 1003.1-200x usually specifies 512. Future releases of BSD are expected to consistently
22035 provide 512 bytes as a default with a way of specifying 1 024-byte units where appropriate.

22036 The <*date and time*> field in the **–l** format is specified only for the POSIX locale. As noted, the
22037 format can be different in other locales. No mechanism for defining this is present in this volume
22038 of IEEE Std. 1003.1-200x, as the appropriate vehicle is a messaging system; that is, the format
22039 should be specified as a ''message''.

22040 **FUTURE DIRECTIONS**

22041 The **–s** uses implementation-defined units and cannot be used portably; it may be withdrawn in
22042 a future issue.

22043 **SEE ALSO**

22044 *chmod*, *find*, the System Interfaces volume of IEEE Std. 1003.1-200x, **<sys/stat.h>**

22045 **CHANGE HISTORY**

22046 First released in Issue 2.

22047 **Issue 4**

22048 Aligned with the ISO / IEC 9945-2: 1993 standard.

22049 **Issue 5**

22050 Second FUTURE DIRECTION added.

22051 **Issue 6**

22052 The following new requirements on POSIX implementations derive from alignment with the
22053 Single UNIX Specification:

22054 • In the **–F** option, other symbols are allowed for other file types.

22055 Treatment of symbolic links is added, as defined in the IEEE P1003.2b draft standard.

NAME

m4 — macro processor (**DEVELOPMENT**)

SYNOPSIS

XSI
```
m4 [-s][-D name[=val]]...[-U name]... file...
```

DESCRIPTION

The *m4* utility is a macro processor that shall read one or more text files, process them according to their included macro statements, and write the results to standard output.

OPTIONS

The *m4* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the **−D** and **−U** options shall be significant.

The following options shall be supported:

−s Enable line synchronization output for the *c99* preprocessor phase (that is, **#line** directives).

−D *name***[**=*val***]**
Define *name* to *val* or to null if =*val* is omitted.

−U *name* Undefine *name*.

OPERANDS

The following operand shall be supported:

file A path name of a text file to be processed. If no *file* is given, or if it is '−', the standard input shall be read.

STDIN

The standard input shall be a text file that is used if no *file* operand is given, or if it is '−'.

INPUT FILES

The input file named by the *file* operand shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *m4*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

22098 **ASYNCHRONOUS EVENTS**
22099 Default.

22100 **STDOUT**
22101 The standard output shall be the same as the input files, after being processed for macro
22102 expansion.

22103 **STDERR**
22104 Used to display strings with the **errprint** macro, macro tracing enabled by the **traceon** macro, the
22105 defined text for macros written by the **dumpdef** macro, or for diagnostic messages.

22106 **OUTPUT FILES**
22107 None.

22108 **EXTENDED DESCRIPTION**
22109 The *m4* utility shall compare each token from the input against the set of built-in and user-
22110 defined macros. If the token matches the name of a macro, then the token shall be replaced by
22111 the macros defining text, if any, and rescanned for matching macro names. Once no portion of
22112 the token matches the name of a macro, it shall be written to standard output. Macros may have
22113 arguments, in which case the arguments shall be substituted into the defining text before it is
22114 rescanned.

22115 Macro calls have the form:

22116 *name*(*arg1, arg2, ..., argn*)

22117 Macro names shall consist of letters, digits, and underscores, where the first character is not a
22118 digit. Tokens not of this form shall not be treated as macro names.

22119 The application shall ensure that the left parenthesis immediately follows the name of the
22120 macro. If a token matching the name of a macro is not followed by a left parenthesis, it is
22121 handled as a use of that macro without arguments.

22122 If a macro name is followed by a left parenthesis, its arguments are the comma-separated tokens
22123 between the left parenthesis and the matching right parenthesis. Unquoted <blank> and
22124 <newline> characters preceding each argument shall be ignored. All other characters, including
22125 trailing <blank> and <newline> characters, are retained. Commas enclosed between left and
22126 right parenthesis characters do not delimit arguments.

22127 Arguments are positionally defined and referenced. The string "$1" in the defining text shall be
22128 replaced by the first argument. Systems shall support at least nine arguments; only the first nine
22129 can be referenced, using the strings "$1" to "$9", inclusive. The string "$0" is replaced with
22130 the name of the macro. The string "$#" is replaced by the number of arguments as a string. The
22131 string "$*" is replaced by a list of all of the arguments, separated by commas. The string "$@"
22132 is replaced by a list of all of the arguments separated by commas, and each argument is quoted
22133 using the current left and right quoting strings.

22134 If fewer arguments are supplied than are in the macro definition, the omitted arguments are
22135 taken to be null. It is not an error if more arguments are supplied than are in the macro
22136 definition.

22137 No special meaning is given to any characters enclosed between matching left and right quoting
22138 strings, but the quoting strings are themselves discarded. By default, the left quoting string
22139 consists of a grave accent (`) and the right quoting string consists of an acute accent (´) see
22140 also the **changequote** macro.

22141 Comments are written but not scanned for matching macro names; by default, the begin-
22142 comment string consists of the number sign character and the end-comment string consists of a
22143 <newline> character. See also the **changecom** and **dnl** macros.

The *m4* utility makes available the following built-in macros. They can be redefined, but once this is done the original meaning is lost. Their values are null unless otherwise stated. In the descriptions below, the term *defining text* refers to the value of the macro: the second argument to the **define** macro, among other things. Except for the first argument to the **eval** macro, all numeric built-in macro arguments shall be interpreted as decimal values. The string values produced as the defining text of the **decr**, **divnum**, **incr**, **index**, **len**, and **sysval** built-in macros shall be in the form of a decimal-constant as defined in the C language.

changecom The **changecom** macro sets the begin-comment and end-comment strings. With no arguments, the comment mechanism is disabled. With a single argument, that argument becomes the begin-comment string and the <newline> character becomes the end-comment string. With two arguments, the first argument becomes the begin-comment string and the second argument becomes the end-comment string. Systems support comment strings of at least five characters.

changequote The **changequote** macro sets the begin-quote and end-quote strings. With no arguments, the quote strings are set to the default values (that is, ‘ ’). With a single argument, that argument becomes the begin-quote string and the <newline> character becomes the end-quote string. With two arguments, the first argument becomes the begin-quote string and the second argument becomes the end-quote string. Systems support quote strings of at least five characters.

decr The defining text of the **decr** macro is its first argument decremented by 1. It is an error to specify an argument containing any non-numeric characters.

define The second argument is specified as the defining text of the macro whose name is the first argument.

defn The defining text of the **defn** macro is the quoted definition (using the current quoting strings) of its arguments.

divert The *m4* utility maintains ten temporary buffers, numbered 0 to 9, inclusive.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

Re D1, XCU, ERN 286: Buffer 0 seems strange: it’s one of the 10 buffers, and thus should be a diversion buffer, but at 19704 it implies that it’s the name of the main output. What is it (or are there really only 9 diversion buffers?) Also, see austin-group mail sequence #295.

When the last of the input has been processed, any output that has been placed in these buffers is written to standard output in buffer-numerical order. The **divert** macro diverts future output to the buffer specified by its argument. Specifying no argument or an argument of 0 resumes the normal output process. Output diverted to a stream other than 0 to 9 is discarded. It is an error to specify an argument containing any non-numeric characters.

divnum The defining text of the **divnum** macro is the number of the current output stream as a string.

dnl The **dnl** macro shall cause *m4* to discard all input characters up to and including the next <newline> character.

dumpdef The **dumpdef** macro writes the defined text to standard error for each of the macros specified as arguments, or, if no arguments are specified, for all macros.

22188 **errprint** The **errprint** macro writes its arguments to standard error.

22189 **eval** The **eval** macro evaluates its first argument as an arithmetic expression, using 32-
22190 bit signed integer arithmetic. All of the C-language operators are supported, except |
22191 for: |

22192 `[]` |
22193 `–>` |
22194 `++` |
22195 `––` |
22196 `(`*`type`*`)` |
22197 `unary *` |
22198 *`sizeof`* |
22199 `,` |
22200 `.` |
22201 `?:` |
22202 `unary &` |

22203 and all assignment operators. It is an error to specify any of these operators. |
22204 Precedence and associativity are as in C. Systems support octal and hexadecimal
22205 numbers as in C. The second argument, if specified, sets the radix for the result; the
22206 default is 10. The third argument, if specified, sets the minimum number of digits
22207 in the result. It is an error to specify the second or third argument containing any
22208 non-numeric characters.

22209 **ifdef** If the first argument to the **ifdef** macro is defined, the defining text is the second
22210 argument. Otherwise, the defining text is the third argument, if specified, or the
22211 null string, if not.

22212 **ifelse** If the first argument (or the defining text of the first argument if it is a macro
22213 name) to the **ifelse** macro is the same as the second argument (or the defining text
22214 of the second argument if it is a macro name), then the defining text is the third
22215 argument.

22216 ***Notes to Reviewers***

22217 *This section with side shading will not appear in the final copy. - Ed.*

22218 D1, XCU, ERN 287 (as modified by email #297) suggests the following replacement
22219 text for **ifelse:** "This function takes 3n+0 or 3n+1 arguments. For each group of 3
22220 arguments, if the first and second are the same, the result is the third of the group.
22221 If the strings are not equal, and no arguments remain, the defining text is null. If
22222 one argument remains, it becomes the defining text. If three or more arguments
22223 remain, the process is repeated with the new group of three arguments. If 3n+2
22224 arguments are provided, the evaluation proceeds as above, but a warning is
22225 generated and the last argument ignored.
22226 If there are more than four arguments, the initial comparison of the first and
22227 second arguments are repeated for each group of three arguments. If no match is
22228 found, the defining text is the argument following the last set of three compared;
22229 otherwise, it is null.

22230 **include** The defining text for the **include** macro is the contents of the file named by the first
22231 argument. It is an error if the file cannot be read.

22232 **incr** The defining text of the **incr** macro is its first argument incremented by 1. It is an
22233 error to specify an argument containing any non-numeric characters.

22234 **index** The defining text of the **index** macro is the first character position (as a string) in
22235 the first argument where a string matching the second argument begins (zero |
22236 origin), or –1 if the second argument does not occur. |

22237 **len** The defining text of the **len** macro is the length (as a string) of the first argument.

22238 **m4exit** Exit from the *m4* utility. If the first argument is specified, it is the exit code. The
22239 default is zero. It is an error to specify an argument containing any non-numeric
22240 characters.

22241 **m4wrap** The first argument is processed when EOF is reached. If the **m4wrap** macro is used
22242 multiple times, the arguments specified are processed in the order in which the
22243 **m4wrap** macros were processed.

22244 **maketemp** The defining text is the first argument, with any trailing 'X' characters replaced
22245 with the current process ID as a string.

22246 **popdef** The **popdef** macro deletes the current definition of its arguments, replacing that |
22247 definition with the previous one. If there is no previous definition, the macro is |
22248 undefined. |

22249 **pushdef** The **pushdef** macro is identical to the **define** macro with the exception that it
22250 preserves any current definition for future retrieval using the **popdef** macro.

22251 **shift** The defining text for the **shift** macro is all of its arguments except for the first one.

22252 **sinclude** The **sinclude** macro is identical to the **include** macro, except that it is not an error
22253 if the file is inaccessible.

22254 **substr** The defining text for the **substr** macro is the substring of the first argument
22255 beginning at the zero-offset character position specified by the second argument.
22256 The third argument, if specified, is the number of characters to select; if not
22257 specified, the characters from the starting point to the end of the first argument
22258 become the defining text. It is not an error to specify a starting point beyond the
22259 end of the first argument and the defining text is null. It is an error to specify an
22260 argument containing any non-numeric characters.

22261 **syscmd** The **syscmd** macro interprets its first argument as a shell command line. The
22262 defining text is the string result of that command. No output redirection is
22263 performed by the *m4* utility. The exit status value from the command can be
22264 retrieved using the **sysval** macro.

22265 **sysval** The defining text of the **sysval** macro is the exit value of the utility last invoked by
22266 the **syscmd** macro (as a string).

22267 **traceon** The **traceon** macro enables tracing for the macros specified as arguments, or, if no
22268 arguments are specified, for all macros. The trace output is written to standard
22269 error in an unspecified format.

22270 **traceoff** The **traceoff** macro disables tracing for the macros specified as arguments, or, if no
22271 arguments are specified, for all macros.

22272 **translit** The defining text of the **translit** macro is the first argument with every character
22273 that occurs in the second argument replaced with the corresponding character
22274 from the third argument.

22275 **undefine** The **undefine** macro deletes all definitions (including those preserved using the
22276 **pushdef** macro) of the macros named by its arguments.

undivert The **undivert** macro shall cause immediate output of any text in temporary buffers named as arguments, or all temporary buffers if no arguments are specified. Buffers can be undiverted into other temporary buffers. Undiverting discards the contents of the temporary buffer. It is an error to specify an argument containing any non-numeric characters.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred

If the **m4exit** macro is used, the exit value can be specified by the input file.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **defn** macro is useful for renaming macros, especially built-ins.

EXAMPLES

An example of a single *m4* input file capable of generating two output files follows. The file **file1.m4** could contain lines such as:

```
if(VER, 1, do_something)
if(VER, 2, do_something)
```

The makefile for the program might include:

```
file1.1.c : file1.m4
            m4 –D VER=1 file1.m4 > file1.1.c
            ...
file1.2.c : file1.m4
            m4 –D VER=2 file1.m4 > file1.2.c
            ...
```

The –**U** option can be used to undefine **VER**. If **file1.m4** contains:

```
if(VER, 1,  do_something)
if(VER, 2,  do_something)
ifndef(VER, do_something)
```

then the makefile would contain:

```
file1.0.c : file1.m4
            m4 –U VER file1.m4 > file1.0.c
            ...
file1.1.c : file1.m4
            m4 –D VER=1 file1.m4 > file1.1.c
            ...
file1.2.c : file1.m4
            m4 –D VER=2 file1.m4 > file1.2.c
            ...
```

RATIONALE

None.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Utility Syntax Guideline support mandated.

Internationalized environment variable support mandated.

Issue 5

The phrase ‘‘the defined text for macros written by the **dumpdef** macro’’ is added to the description of STDERR, and the description of **dumpdef** is updated to indicate that output is written to standard error. The description of **eval** is updated to indicate that the list of excluded C operators excludes unary `'&'` and `'.'`. In the description of **ifdef**, the phrase ‘‘and it is not defined to be zero’’ is deleted.

Issue 6

In the EXTENDED DESCRIPTION, the **eval** text is updated to include a `'&'` character in the excepted list.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

The Open Group Base Resolution bwg2000-006 is applied.

22340 **NAME**

22341 mailx — process messages

22342 **SYNOPSIS**

22343 **Send Mode**

22344 `mailx [–s` *`subject`*`] address...`

22345 **Receive Mode**

22346 `mailx –e`

22347 `mailx [–HiNn][–F][–u` *`user`*`]`

22348 `mailx –f[–HiNn][–F][`*`file`*`]`

22349 **DESCRIPTION**

22350 The *mailx* utility provides a message sending and receiving facility. It has two major modes,
22351 selected by the options used: Send Mode and Receive Mode.

22352 On systems that do not support the User Portability Utilities option, an application using *mailx*
22353 shall have the ability to send messages in an unspecified manner (Send Mode). Unless the first
22354 character of one or more lines is tilde (`'~'`), all characters in the input message shall appear in
22355 the delivered message, but additional characters may be inserted in the message before it is
22356 retrieved.

22357 On systems supporting the User Portability Utilities option, mail-receiving capabilities and other
22358 interactive features, Receive Mode, described below, also shall be enabled.

22359 **Send Mode**

22360 Send Mode can be used by applications or users to send messages from the text in standard
22361 input.

22362 **Receive Mode**

22363 Receive Mode is more oriented to interactive users. Mail can be read and sent in this interactive
22364 mode.

22365 When reading mail, *mailx* provides commands to facilitate saving, deleting, and responding to
22366 messages. When sending mail, *mailx* allows editing, reviewing, and other modification of the
22367 message as it is entered.

22368 Incoming mail shall be stored in one or more unspecified locations for each user, collectively
22369 called the system *mailbox* for that user. When *mailx* is invoked in Receive Mode, the system
22370 mailbox shall be the default place to find new mail. As messages are read, they shall be marked
22371 to be moved to a secondary file for storage, unless specific action is taken. This secondary file is
22372 called the **mbox** and is normally located in the directory referred to by the *HOME* environment
22373 variable (see *MBOX* in the ENVIRONMENT VARIABLES section for a description of this file).
22374 Messages shall remain in this file until explicitly removed. When the **–f** option is used to read
22375 mail messages from secondary files, messages shall be retained in those files unless specifically
22376 removed. All three of these locations—system mailbox, **mbox**, and secondary file—are referred
22377 to in this section as simply ‘‘mailboxes’’, unless more specific identification is required.

OPTIONS

The *mailx* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported. (Only the **–s** *subject* option shall be required on all systems. The other options are required only on systems supporting the User Portability Utilities option.)

–e Test for the presence of mail in the system mailbox. The *mailx* utility shall write nothing and exit with a successful return code if there is mail to read.

–f Read messages from the file named by the *file* operand instead of the system mailbox. (See also **folder**.) If no *file* operand is specified, read messages from the **mbox** instead of the system mailbox.

–F Record the message in a file named after the first recipient. The name is the login-name portion of the address found first on the **To:** line in the mail header. Overrides the **record** variable, if set (see **Internal Variables in mailx** (on page 2801).)

–H Write a header summary only.

–i Ignore interrupts. (See also **ignore**).

–n Do not initialize from the system default start-up file. See the EXTENDED DESCRIPTION section.

–N Do not write an initial header summary.

–s *subject* Set the **Subject** header field to *subject*. All characters in the *subject* string shall appear in the delivered message. The results are unspecified if *subject* is longer than {LINE_MAX} – 10 bytes or contains a <newline> character.

–u *user* Read the system mailbox of the login name *user*. This shall only be successful if the invoking user has the appropriate privileges to read the system mailbox of that user.

OPERANDS

The following operands shall be supported:

address Addressee of message. When **–n** is specified and no user start-up files are accessed (see the EXTENDED DESCRIPTION section), the user or application shall ensure this is an address to pass to the mail delivery system. Any system or user start-up files may enable aliases (see **alias** under **Commands in mailx** (on page 2804)) that may modify the form of *address* before it is passed to the mail delivery system.

file A path name of a file to be read instead of the system mailbox when **–f** is specified. The meaning of the *file* option-argument shall be affected by the contents of the **folder** internal variable; see **Internal Variables in mailx** (on page 2801).

STDIN

When *mailx* is invoked in Send Mode (the first synopsis line), standard input shall be the message to be delivered to the specified addresses. When in Receive Mode, user commands are accepted from *stdin*. If the User Portability Utilities option is not supported, standard input lines beginning with a tilde (′~′) character produce unspecified results.

If the User Portability Utilities option is supported, then in both Send and Receive Modes, standard input lines beginning with the escape character (usually tilde (′~′)) affect processing as described in **Command Escapes in mailx** (on page 2812).

INPUT FILES

When *mailx* is used as described by this volume of IEEE Std. 1003.1-200x, the *file* option-argument (see the **−f** option) and the **mbox** shall be text files containing mail messages, formatted as described in the OUTPUT FILES section. The nature of the system mailbox is unspecified; it need not be a file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mailx*:

DEAD Determine the path name of the file in which to save partial messages in case of interrupts or delivery errors. The default shall be **dead.letter** in the directory named by the *HOME* variable. The behavior of *mailx* in saving partial messages is unspecified if the User Portability Utilities option is not supported and *DEAD* is not defined with the value **/dev/null**.

EDITOR Determine the name of a utility to invoke when the **edit** (see **Commands in mailx** (on page 2804)) or **~e** (see **Command Escapes in mailx** (on page 2812)) command is used. The default editor is unspecified. XSI On XSI-conformant systems it is *ed*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

HOME Determine the path name of the user's home directory.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the handling of case-insensitive address and header-field comparisons.

LC_TIME Determine the format and contents of the date and time strings written by *mailx*.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LISTER Determine a string representing the command for writing the contents of the **folder** directory to standard output when the **folders** command is given (see **folders** in **Commands in mailx** (on page 2804)). Any string acceptable as a *command_string* operand to the *sh* **−c** command shall be valid. If this variable is null or not set, the output command shall be *ls*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

MAILRC Determine the path name of the start-up file. The default shall be **.mailrc** in the directory referred to by the *HOME* environment variable. The behavior of *mailx* is unspecified if the User Portability Utilities option is not supported and *MAILRC* is not defined with the value **/dev/null**.

MBOX Determine a path name of the file to save messages from the system mailbox that have been read. The **exit** command shall override this function, as shall saving the

message explicitly in another file. The default shall be **mbox** in the directory named by the *HOME* variable. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PAGER Determine a string representing an output filtering or pagination command for writing the output to the terminal. Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. When standard output is a terminal device, the message output shall be piped through the command if the *mailx* internal variable **crt** is set to a value less the number of lines in the message; see **Internal Variables in mailx** (on page 2801). If the *PAGER* variable is null or not set, the paginator shall be either *more* or another paginator utility documented in the system documentation. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

SHELL Determine the name of a preferred command interpreter. The default shall be *sh*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

TERM Determine the name of the terminal type, to indicate in an unspecified manner, if the internal variable **screen** is not specified, the number of lines in a screenful of headers. If *TERM* is not set or is set to null, an unspecified default terminal type shall be used and the value of a screenful is unspecified. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

VISUAL Determine a path name of a utility to invoke when the **visual** command (see **Commands in mailx** (on page 2804)) or **~v** command-escape (see **Command Escapes in mailx** (on page 2812)) is used. If this variable is null or not set, the full-screen editor shall be *vi*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

ASYNCHRONOUS EVENTS

When *mailx* is in Send Mode and standard input is not a terminal, it shall take the standard action for all signals.

In Receive Mode, or in Send Mode when standard input is a terminal, if a SIGINT signal is received:

1. If in command mode, the current command, if there is one, shall be aborted, and a command-mode prompt shall be written.
2. If in input mode:
   a. If **ignore** is set, *mailx* shall write "@\n", discard the current input line, and continue processing, bypassing the message-abort mechanism described in item 2b.
   b. If the interrupt was received while sending mail, either when in Receive Mode or in Send Mode, a message shall be written, and another subsequent interrupt, with no other intervening characters typed, shall be required to abort the mail message. If in Receive Mode and another interrupt is received, a command-mode prompt shall be written. If in Send Mode and another interrupt is received, *mailx* shall terminate with a non-zero status.

      In both cases listed in item b, if the message is not empty:

      i. If **save** is enabled and the file named by *DEAD* can be created, the message shall be written to the file named by *DEAD*. If the file exists, the message shall be written to replace the contents of the file.

ii. If **save** is not enabled, or the file named by *DEAD* cannot be created, the message shall not be saved.

The *mailx* utility shall take the standard action for all other signals.

STDOUT

In command and input modes, all output, including prompts and messages, shall be written to standard output.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

Various *mailx* commands and command escapes can create or add to files, including the **mbox**, the dead-letter file, and secondary mailboxes. When *mailx* is used as described in this volume of IEEE Std. 1003.1-200x, these files shall be text files, formatted as follows:

```
line beginning with From<space>
[one or more header-lines; see Commands in mailx (on page 2804)]
empty line
[zero or more body lines
empty line]
[line beginning with From<space>...]
```

where each message begins with the **From <space>** line shown, preceded by the beginning of the file or an empty line. (The **From <space>** line is considered to be part of the message header, but not one of the header-lines referred to in **Commands in mailx** (on page 2804); thus, it shall not be affected by the **discard**, **ignore**, or **retain** commands.) The formats of the remainder of the **From <space>** line and any additional header lines are unspecified, except that none shall be empty. The format of a message body line is also unspecified, except that no line following an empty line shall start with **From <space>**; *mailx* shall modify any such user-entered message body lines (following an empty line and beginning with **From <space>**) by adding one or more characters to precede the 'F'; it may add these characters to **From <space>** lines that are not preceded by an empty line.

When a message from the system mailbox or entered by the user is not a text file, it is implementation-defined how such a message is stored in files written by *mailx*.

EXTENDED DESCRIPTION

The entire EXTENDED DESCRIPTION section shall apply only to implementations supporting the User Portability Utilities option.

The *mailx* utility cannot guarantee support for all character encodings in all circumstances. For example, inter-system mail may be restricted to 7-bit data by the underlying network, 8-bit data need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used.

When *mailx* is invoked using one of the Receive Mode synopsis forms, it shall write a page of header-summary lines (if **–N** was not specified and there are messages, see below), followed by a prompt indicating that *mailx* can accept regular commands (see **Commands in mailx** (on page 2804)); this is termed *command mode*. The page of header-summary lines shall contain the first new message if there are new messages, or the first unread message if there are unread messages, or the first message. When *mailx* is invoked using the Send Mode synopsis and standard input is a terminal, if no subject is specified on the command line and the **asksub** variable is set, a prompt for the subject shall be written. At this point, *mailx* is in input mode. This input mode is also entered when using one of the Receive Mode synopsis forms and a reply

or new message is composed using the **reply**, **Reply**, **followup**, **Followup**, or **mail** commands and standard input is a terminal. When the message is typed and the end of message is encountered, the message shall be passed to the mail delivery software. Commands can be entered by beginning a line with the escape character (by default, tilde (`'~'`)) followed by a single command letter and optional arguments. See **Commands in mailx** (on page 2804) for a summary of these commands. It is unspecified what effect these commands will have if standard input is not a terminal when a message is entered using either the Send Mode synopsis, or the Read Mode commands **reply**, **Reply**, **followup**, **Followup**, or **mail**.

Note: For notational convenience, this section uses the default escape character, tilde, in all references and examples.

At any time, the behavior of *mailx* shall be governed by a set of environmental and internal variables. These are flags and valued parameters that can be set and cleared via the *mailx* **set** and **unset** commands.

Regular commands are of the form:

[*command***] [***msglist***] [***argument ...***]**

If no *command* is specified in command mode, **next** shall be assumed. In input mode, commands shall be recognized by the escape character, and lines not treated as commands shall be taken as input for the message.

In command mode, each message shall be assigned a sequential number, starting with 1.

All messages have a state that affects how they are displayed in the header summary and how they are retained or deleted upon termination of *mailx*. There is at any time the notion of a *current* message, marked by a `'>'` at the beginning of a line in the header summary. When *mailx* is invoked using one of the Receive Mode synopsis forms, the current message shall be the first new message, if there is a new message, or the first unread message if there is an unread message, or the first message if there are any messages, or unspecified if there are no messages in the mailbox. Each command that takes an optional list of messages (*msglist*) or an optional single message (*message*) on which to operate shall leave the current message set to the highest-numbered message of the messages specified, unless the command deletes messages, in which case the current message shall be set to the first undeleted message (that is, a message not in the deleted state) after the highest-numbered message deleted by the command, if one exists, or the first undeleted message before the highest-numbered message deleted by the command, if one exists, or to an unspecified value if there are no remaining undeleted messages. All messages are in one of the following states:

new The message is present in the system mailbox and has not been viewed by the user or moved to any other state. Messages in state *new* when *mailx* quits shall be retained in the system mailbox.

unread The message has been present in the system mailbox for more than one invocation of *mailx* and has not been viewed by the user or moved to any other state. Messages in state *unread* when *mailx* quits shall be retained in the system mailbox.

read The message has been processed by one of the following commands: **~f**, **~m**, **~F**, **~M**, **copy**, **mbox**, **next**, **pipe**, **print**, **Print**, **top**, **type**, **Type**, **undelete**. The **delete**, **dp**, and **dt** commands may also cause the next message to be marked as *read*, depending on the value of the **autoprint** variable. Messages that are in the system mailbox and in state *read* when *mailx* quits shall be saved in the **mbox**, unless the internal variable **hold** was set. Messages that are in the **mbox** or in a secondary mailbox and in state *read* when *mailx* quits shall be retained in their current location.

22607 *deleted* The message has been processed by one of the following commands: **delete**, **dp**,
22608 **dt**. Messages in state *deleted* when *mailx* quits shall be deleted. Deleted messages
22609 shall be ignored until *mailx* quits or changes mailboxes or they are specified to the
22610 undelete command; for example, the message specification /*string* shall only
22611 search the subject lines of messages that have not yet been deleted, unless the
22612 command operating on the list of messages is **undelete**. No deleted message or
22613 deleted message header shall be displayed by any *mailx* command other than
22614 **undelete**.

22615 *preserved* The message has been processed by a **preserve** command. When *mailx* quits, the
22616 message shall be retained in its current location.

22617 *saved* The message has been processed by one of the following commands: **save** or
22618 **write**. If the current mailbox is the system mailbox, and the internal variable
22619 **keepsave** is set, messages in the state saved shall be saved to the file designated by
22620 the *MBOX* variable (see the ENVIRONMENT VARIABLES section). If the current
22621 mailbox is the system mailbox, messages in the state *saved* shall be deleted from
22622 the current mailbox, when the **quit** or **file** command is used to exit the current
22623 mailbox.

22624 The header-summary line for each message shall indicate the state of the message.

22625 Many commands take an optional list of messages (*msglist*) on which to operate, which defaults
22626 to the current message. A *msglist* is a list of message specifications separated by <blank>
22627 characters, which can include:

22628 `n` Message number *n*.

22629 `+` The next undeleted message, or the next deleted message for the **undelete** command.

22630 – The next previous undeleted message, or the next previous deleted message for the
22631 **undelete** command.

22632 `.` The current message.

22633 `^` The first undeleted message, or the first deleted message for the **undelete** command.

22634 `$` The last message.

22635 `*` All messages.

22636 `n-m` An inclusive range of message numbers.

22637 *address* All messages from *address*; any address as shown in a header summary shall be
22638 matchable in this form.

22639 /*string* All messages with *string* in the subject line (case ignored).

22640 `:c` All messages of type *c*, where *c* shall be one of:

22641 `d` Deleted messages.

22642 `n` New messages.

22643 `o` Old messages (any not in state *read* or *new*).

22644 `r` Read messages.

22645 `u` Unread messages.

22646 Other commands take an optional message (*message*) on which to operate, which defaults to the
22647 current message. All of the forms allowed for *msglist* are also allowed for *message*, but if more
22648 than one message is specified, only the first shall be operated on.

Other arguments are usually arbitrary strings whose usage depends on the command involved.

Start-Up in mailx

At start-up time, *mailx* shall take the following steps in sequence:

1. Establish all variables at their stated default values.
2. Process command line options, overriding corresponding default values.
3. Import any of the *DEAD*, *EDITOR*, *MBOX*, *LISTER*, *PAGER*, *SHELL*, or *VISUAL* variables that are present in the environment, overriding the corresponding default values.
4. Read *mailx* commands from an unspecified system start-up file, unless the **−n** option is given, to initialize any internal *mailx* variables and aliases.
5. Process the start-up file of *mailx* commands named in the user *MAILRC* variable.

Most regular *mailx* commands are valid inside start-up files, the most common use being to set up initial display options and alias lists. The following commands shall be invalid in the start-up file: **!**, **edit**, **hold**, **mail**, **preserve**, **reply**, **Reply**, **shell**, **visual**, **Copy**, **followup**, and **Followup**. Any errors in the start-up file shall either cause *mailx* to terminate with a diagnostic message and a non-zero status or to continue after writing a diagnostic message, ignoring the remainder of the lines in the start-up file.

A blank line in a start-up file shall be ignored.

Internal Variables in mailx

The following variables are internal *mailx* variables. Each internal variable can be set via the *mailx* **set** command at any time. The **unset** and **set no** *name* commands can be used to erase variables.

In the following list, variables shown as:

`variable`

represent Boolean values. Variables shown as:

`variable=`*`value`*

shall be assigned string or numeric values. For string values, the rules in **Commands in mailx** (on page 2804) concerning file names and quoting also apply.

The defaults specified here may be changed by the implementation-defined system start-up file unless the user specifies the **−n** option.

allnet All network names whose login name components match are treated as identical. This shall cause the *msglist* message specifications to behave similarly. The default shall be **noallnet**. See also the **alternates** command and the **metoo** variable.

append Append messages to the end of the **mbox** file upon termination instead of placing them at the beginning. The default shall be **noappend**. This variable shall not affect the **save** command when saving to the **mbox**.

ask, **asksub**
Prompt for a subject line on outgoing mail if one is not specified on the command line with the **−s** option. The **ask** and **asksub** forms are synonyms; the system shall refer to **asksub** and **noasksub** in its messages, but shall accept **ask** and **noask** as user input to mean **asksub** and **noasksub**. It shall not be possible to set both **ask** and **noasksub**, or **noask** and **asksub**. The default shall be **asksub**, but no

22690 prompting shall be done if standard input is not a terminal.

22691 **askbcc** Prompt for the blind copy list. The default shall be **noaskbcc**.

22692 **askcc** Prompt for the copy list. The default shall be **noaskcc**.

22693 **autoprint** Enable automatic writing of messages after **delete** and **undelete** commands. The
22694 default shall be **noautoprint**.

22695 **bang** Enable the special-case treatment of exclamation marks (`'!'`) in escape command |
22696 lines; see the **escape** command and **Command Escapes in mailx** (on page 2812).
22697 The default shall be **nobang**, disabling the expansion of `'!'` in the *command*
22698 argument to the **~!** command and the **~<!***command* escape.

22699 **cmd**=*command*
22700 Set the default command to be invoked by the **pipe** command. The default shall be
22701 **nocmd**.

22702 **crt**=*number* Pipe messages having more than *number* lines through the command specified by
22703 the value of the *PAGER* variable. The default shall be **nocrt**. If it is set to null, the |
22704 value used is implementation-defined. |

22705 XSI **debug** Enable verbose diagnostics for debugging. Messages are not delivered. The
22706 default shall be **nodebug**.

22707 **dot** When **dot** is set, a period on a line by itself during message input from a terminal
22708 shall also signify end-of-file (in addition to normal end-of-file). The default shall be
22709 **nodot**. If **ignoreeof** is set (see below), a setting of **nodot** shall be ignored and the |
22710 period is the only method to terminate input mode.

22711 **escape**=*c* Set the command escape character to be the character `'c'`. By default, the
22712 command escape character shall be tilde. If **escape** is unset, tilde shall be used; if it
22713 is set to null, command escaping shall be disabled.

22714 **flipr** Reverse the meanings of the **R** and **r** commands. The default shall be **noflipr**.

22715 **folder**=*directory*
22716 The default directory for saving mail files. User-specified file names beginning
22717 with a plus sign (`'+'`) shall be expanded by preceding the file name with this
22718 directory name to obtain the real path name. If *directory* does not start with a slash
22719 (`'/'`), the contents of *HOME* shall be prefixed to it. The default shall be **nofolder**.
22720 If **folder** is unset or set to null, user-specified file names beginning with `'+'` shall
22721 refer to files in the current directory that begin with the literal `'+'` character. See
22722 also **outfolder** below. The **folder** value need not affect the processing of the files
22723 named in *MBOX* and *DEAD*.

22724 **header** Enable writing of the header summary when entering *mailx* in Receive Mode. The
22725 default shall be **header**.

22726 **hold** Preserve all messages that are read in the system mailbox instead of putting them
22727 in the **mbox** save file. The default shall be **nohold**.

22728 **ignore** Ignore interrupts while entering messages. The default shall be **noignore**. |

22729 **ignoreeof** Ignore normal end-of-file during message input. Input can be terminated only by |
22730 entering a period (`'.'`) on a line by itself or by the **~.** command escape. The default
22731 shall be **noignoreeof**. See also **dot** above.

22732 **indentprefix**=*string*
22733 A string that shall be added as a prefix to each line that is inserted into the message

by the **~m** command escape. This variable shall default to one <tab> character.

keep When a system mailbox, secondary mailbox, or **mbox** is empty, truncate it to zero length instead of removing it. The default shall be **nokeep**.

keepsave Keep the messages that have been saved from the system mailbox into other files in the file designated by the variable *MBOX*, instead of deleting them. The default shall be **nokeepsave**.

metoo Suppress the deletion of the login name of the user from the recipient list when replying to a message or sending to a group. The default shall be **nometoo**.

XSI **onehop** When responding to a message that was originally sent to several recipients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). The default shall be **noonehop**.

outfolder Cause the files used to record outgoing messages to be located in the directory specified by the **folder** variable unless the path name is absolute. The default shall be **nooutfolder**. See the **record** variable.

page Insert a <form-feed> after each message sent through the pipe created by the **pipe** command. The default shall be **nopage**.

prompt=*string*
Set the command-mode prompt to *string*. If *string* is null or if **noprompt** is set, no prompting shall occur. The default shall be to prompt with the string `"? "`.

quiet Refrain from writing the opening message and version when entering *mailx*. The default shall be **noquiet**.

record=*file* Record all outgoing mail in the file with the path name *file*. The default shall be **norecord**. See also **outfolder** above.

save Enable saving of messages in the dead-letter file on interrupt or delivery error. See the variable *DEAD* for the location of the dead-letter file. The default shall be **save**.

screen=*number*
Set the number of lines in a screenful of headers for the **headers** and **z** commands. If **screen** is not specified, a value based on the terminal type identified by the *TERM* environment variable, the window size, the baud rate, or some combination of these shall be used.

sendwait Wait for the background mailer to finish before returning. The default shall be **nosendwait**.

showto When the sender of the message was the user who is invoking *mailx*, write the information from the **To:** line instead of the **From:** line in the header summary. The default shall be **noshowto**.

sign=*string* Set the variable inserted into the text of a message when the **~a** command escape is given. The default shall be **nosign**. The character sequences `'\t'` and `'\n'` shall be recognized in the variable as <tab> and <newline> characters, respectively. (See also **~i** in **Command Escapes in mailx** (on page 2812).)

Sign=*string* Set the variable inserted into the text of a message when the **~A** command escape is given. The default shall be **noSign**. The character sequences `'\t'` and `'\n'` shall be recognized in the variable as <tab> and <newline> characters, respectively.

22778 **toplines**=*number*
22779 Set the number of lines of the message to write with the **top** command. The default
22780 shall be 5.

22781 **Commands in mailx**

22782 The following *mailx* commands shall be provided. In the following list, header refers to lines
22783 from the message header, as shown in the OUTPUT FILES section. Header-line refers to lines
22784 within the header that begin with one or more non-white-space characters, immediately
22785 followed by a colon and white space and continuing until the next line beginning with a non-
22786 white-space character or an empty line. Header-field refers to the portion of a header line prior
22787 to the first colon in that line.

22788 For each of the commands listed below, the command can be entered as the abbreviation (those
22789 characters in the Synopsis command word preceding the '[', the full command (all characters
22790 shown for the command word, omitting the '[' and ']', or any truncation of the full
22791 command down to the abbreviation. For example, the **exit** command (shown as **ex[it]** in the
22792 Synopsis) can be entered as **ex**, **exi**, or **exit**.

22793 The arguments to commands can be quoted, using the following methods:

22794 • An argument can be enclosed between paired double-quotes (" ") or single-quotes (' '); any |
22795 white space, shell word expansion, or backslash characters within the quotes shall be treated
22796 literally as part of the argument. A double-quote shall be treated literally within single-
22797 quotes and *vice versa*. These special properties of the quote marks shall occur only when they
22798 are paired at the beginning and end of the argument.

22799 • A backslash outside of the enclosing quotes shall be discarded and the following character
22800 treated literally as part of the argument.

22801 • An unquoted backslash at the end of a command line shall be discarded and the next line
22802 shall continue the command.

22803 File names, where expected, shall be subjected to the process of shell word expansions (see
22804 Section 2.6 (on page 2244)); if more than a single path name results and the command is
22805 expecting one file, the effects are unspecified. If the file name begins with an unquoted plus sign,
22806 it shall not be expanded, but treated as the named file (less the leading plus) in the **folder**
22807 directory. (See the **folder** variable.)

22808 **Declare Aliases**

22809 *Synopsis*: `a[lias] [`*`alias`*` [`*`address...`*`]]`
22810 `g[roup] [`*`alias`*` [`*`address...`*`]]`

22811 Add the given addresses to the alias specified by *alias*. The names shall be substituted when
22812 *alias* is used as a recipient address specified by the user in an outgoing message (that is, other
22813 recipients addressed indirectly through the **reply** command shall not be substituted in this
22814 manner). Mail address alias substitution shall apply only when the alias string is used as a full
22815 address; for example, when **hlj** is an alias, *hlj@posix.com* does not trigger the alias substitution. If
22816 no arguments are given, write a listing of the current aliases to standard output. If only an *alias*
22817 argument is given, write a listing of the specified alias to standard output. These listings need
22818 not reflect the same order of addresses that were entered.

22819 **Declare Alternatives**

22820 *Synopsis*: `alt[ernates] name...`

22821 (See also the **metoo** command.) Declare a list of alternative names for the user's login. When
22822 responding to a message, these names shall be removed from the list of recipients for the
22823 response. The comparison of names shall be in a case-insensitive manner. With no arguments,
22824 **alternates** shall write the current list of alternative names.

22825 **Change Current Directory**

22826 *Synopsis*: `cd [directory]`
22827 `ch[dir] [directory]`

22828 Change directory. If *directory* is not specified, the contents of *HOME* shall be used.

22829 **Copy Messages**

22830 *Synopsis*: `c[opy] [file]`
22831 `c[opy] [msglist] file`
22832 `C[opy] [msglist]`

22833 Copy messages to the file named by the path name *file* without marking the messages as saved.
22834 Otherwise, it shall be equivalent to the **save** command.

22835 In the capitalized form, save the specified messages in a file whose name is derived from the
22836 author of the message to be saved, without marking the messages as saved. Otherwise, it shall
22837 be equivalent to the **Save** command.

22838 **Delete Messages**

22839 *Synopsis*: `d[elete] [msglist]`

22840 Mark messages for deletion from the mailbox. The deletions shall not occur until *mailx* quits (see
22841 the **quit** command) or changes mailboxes (see the **folder** command). If **autoprint** is set and there
22842 are messages remaining after the **delete** command, the current message shall be written as
22843 described for the **print** command (see the **print** command); otherwise, the *mailx* prompt shall be
22844 written.

22845 **Discard Header Fields**

22846 *Synopsis*: `di[scard] [header-field...]`
22847 `ig[nore] [header-field...]`

22848 Suppress the specified header fields when writing messages. Specified *header-fields* shall be
22849 added to the list of suppressed header fields. Examples of header fields to ignore are **status** and
22850 **cc**. The fields shall be included when the message is saved. The **Print** and **Type** commands shall
22851 override this command. The comparison of header fields shall be in a case-insensitive manner. If
22852 no arguments are specified, write a list of the currently suppressed header fields to standard
22853 output; the listing need not reflect the same order of header fields that were entered.

22854 If both **retain** and **discard** commands are given, **discard** commands shall be ignored.

22855 **Delete Messages and Display**

22856 *Synopsis*: `dp [`*`msglist`*`]`
22857 `dt [`*`msglist`*`]`

22858 Delete the specified messages as described for the **delete** command, except that the **autoprint**
22859 variable shall have no effect, and the current message shall be written only if it was set to a
22860 message after the last message deleted by the command. Otherwise, an informational message
22861 to the effect that there are no further messages in the mailbox shall be written, followed by the
22862 *mailx* prompt.

22863 **Echo a String**

22864 *Synopsis*: `ec[ho]` *`string ...`*

22865 Echo the given strings, equivalent to the shell *echo* utility.

22866 **Edit Messages**

22867 *Synopsis*: `e[dit] [`*`msglist`*`]`

22868 Edit the given messages. The messages shall be placed in a temporary file and the utility named
22869 by the *EDITOR* variable is invoked to edit each file in sequence. The default *EDITOR* is
22870 unspecified.

22871 The **edit** command does not modify the contents of those messages in the mailbox.

22872 **Exit**

22873 *Synopsis*: `ex[it]`
22874 `x[it]`

22875 Exit from *mailx* without changing the mailbox. No messages shall be saved in the **mbox** (see also
22876 **quit**).

22877 **Change Folder**

22878 *Synopsis*: `fi[le] [`*`file`*`]`
22879 `fold[er] [`*`file`*`]`

22880 Quit (see the **quit** command) from the current file of messages and read in the file named by the
22881 path name *file*. If no argument is given, the name and status of the current mailbox shall be
22882 written.

22883 Several unquoted special characters shall be recognized when used as *file* names, with the
22884 following substitutions:

22885 `%` The system mailbox for the invoking user.

22886 `%`*`user`* The system mailbox for *user*.

22887 `#` The previous file.

22888 `&` The current **mbox**.

22889 `+`*`file`* The named file in the **folder** directory. (See the **folder** variable.)

22890 The default file shall be the current mailbox.

22891 **Display List of Folders**

22892 *Synopsis*: `folders`

22893 Write the names of the files in the directory set by the **folder** variable. The command specified by
22894 the *LISTER* environment variable shall be used (see the ENVIRONMENT VARIABLES section).

22895 **Follow Up Specified Messages**

22896 ***Notes to Reviewers***

22897 *This section with side shading will not appear in the final copy. - Ed.*

22898 D1, XCU, ERN 300 says that it appears the second sentence below applies to both forms. |

22899 *Synopsis*: `fo[llowup] [`*`message`*`]` |
22900 `F[ollowup] [`*`msglist`*`]`

22901 In the lowercase form, respond to a message, recording the response in a file whose name is
22902 derived from the author of the message. Overrides the **record** variable, if set. See also the **save**
22903 and **copy** commands and **outfolder**.

22904 In the capitalized form, respond to the first message in the *msglist*, sending the message to the
22905 author of each message in the *msglist*. The subject line shall be taken from the first message and
22906 the response shall be recorded in a file whose name is derived from the author of the first
22907 message. See also the **Save** and **Copy** commands and **outfolder**. |

22908 **Display Header Summary for Specified Messages**

22909 *Synopsis*: `f[rom] [`*`msglist`*`]`

22910 Write the header summary for the specified messages.

22911 **Display Header Summary**

22912 *Synopsis*: `h[eaders] [`*`message`*`]`

22913 Write the page of headers that includes the message specified. If the *message* argument is not
22914 specified, the current message shall not change. However, if the *message* argument is specified,
22915 the current message shall become the message that appears at the top of the page of headers that
22916 includes the message specified. The **screen** variable sets the number of headers per page. See
22917 also the **z** command.

22918 **Help**

22919 *Synopsis*: `hel[p]`
22920 `?`

22921 Write a summary of commands.

22922 **Hold Messages**

22923 *Synopsis*: `ho[ld] [`*`msglist`*`]`
22924 `pre[serve] [`*`msglist`*`]`

22925 Mark the messages in *msglist* to be retained in the mailbox when *mailx* terminates. This shall
22926 override any commands that might previously have marked the messages to be deleted. During
22927 the current invocation of *mailx*, only the **delete**, **dp**, or **dt** commands shall remove the *preserve*
22928 marking of a message.

22929 **Execute Commands Conditionally**

22930 *Synopsis*: `i[f] s|r`
22931 *`mail-command`*`s`
22932 `el[se]`
22933 *`mail-command`*`s`
22934 `en[dif]`

22935 Execute commands conditionally, where **if s** executes the following *mail-command*s, up to an
22936 **else** or **endif**, if the program is in Send Mode, and **if r** shall cause the *mail-command*s to be
22937 executed only in Receive Mode.

22938 **List Available Commands**

22939 *Synopsis*: `l[ist]`

22940 Write a list of all commands available. No explanation shall be given.

22941 **Mail a Message**

22942 *Synopsis*: `m[ail]` *`address...`*

22943 Mail a message to the specified addresses or aliases.

22944 **Direct Messages to mbox**

22945 *Synopsis*: `mb[ox] [`*`msglist`*`]`

22946 Arrange for the given messages to end up in the **mbox** save file when *mailx* terminates normally.
22947 See *MBOX*. See also the **exit** and **quit** commands.

22948 **Process Next Specified Message**

22949 *Synopsis*: `n[ext] [`*`message`*`]`

22950 If the current message has not been written (for example, by the **print** command) since *mailx*
22951 started or since any other message was the current message, behave as if the **print** command
22952 was entered. Otherwise, if there is an undeleted message after the current message, make it the
22953 current message and behave as if the **print** command was entered. Otherwise, an informational
22954 message to the effect that there are no further messages in the mailbox shall be written, followed
22955 by the *mailx* prompt.

22956 **Pipe Message**

22957 *Synopsis*: `pi[pe] [[`*`msglist`*`] `*`command`*`]`
22958 `| [[`*`msglist`*`] `*`command`*`]`

22959 Pipe the messages through the given *command* by invoking the command interpreter specified
22960 by *SHELL* with two arguments: **–c** and *command*. (See also *sh* **–c**.) The application shall ensure
22961 that the command is given as a single argument. Quoting, described previously, can be used to
22962 accomplish this. If no arguments are given, the current message shall be piped through the
22963 command specified by the value of the **cmd** variable. If the **page** variable is set, a <form-feed>
22964 character shall be inserted after each message.

22965 **Display Message with Headers**

22966 *Synopsis*: `P[rint] [`*`msglist`*`]`
22967 `T[ype] [`*`msglist`*`]`

22968 Write the specified messages, including all header lines, to standard output. Override
22969 suppression of lines by the **discard**, **ignore**, and **retain** commands. If **crt** is set, the messages
22970 longer than the number of lines specified by the **crt** variable shall be paged through the
22971 command specified by the *PAGER* environment variable.

22972 **Display Message**

22973 *Synopsis*: `p[rint] [`*`msglist`*`]`
22974 `t[ype] [`*`msglist`*`]`

22975 Write the specified messages to standard output. If **crt** is set, the messages longer than the
22976 number of lines specified by the **crt** variable shall be paged through the command specified by
22977 the *PAGER* environment variable.

22978 **Quit**

22979 *Synopsis*: `q[uit]`
22980 *`end-of-file`*

22981 Terminate *mailx*, storing messages that were read in **mbox** (if the current mailbox is the system
22982 mailbox and unless **hold** is set), deleting messages that have been explicitly saved (unless
22983 **keepsave** is set), discarding messages that have been deleted, and saving all remaining messages
22984 in the mailbox.

22985 **Reply to a Message List**

22986 *Synopsis*: `R[eply] [`*`msglist`*`]`
22987 `R[espond] [`*`msglist`*`]`

22988 Mail a reply message to the sender of each message in the *msglist*. The subject line shall be
22989 formed by concatenating **Re:**<space> (unless it already begins with that string) and the subject
22990 from the first message. If **record** is set to a file name, the response shall be saved at the end of
22991 that file.

22992 See also the **flipr** variable.

22993 **Reply to a Message**

22994 *Synopsis*: `r[eply] [`*`message`*`]`
22995 `r[espond] [`*`message`*`]`

22996 Mail a reply message to all recipients included in the header of the message. The subject line
22997 shall be formed by concatenating **Re:**<space> (unless it already begins with that string) and the
22998 subject from the message. If **record** is set to a file name, the response shall be saved at the end of
22999 that file.

23000 See also the **flipr** variable.

23001 **Retain Header Fields**

23002 *Synopsis*: `ret[ain] [`*`header-field`*`...]`

23003 Retain the specified header fields when writing messages. This command shall override all
23004 **discard** and **ignore** commands. The comparison of header fields shall be in a case-insensitive
23005 manner. If no arguments are specified, write a list of the currently retained header fields to
23006 standard output; the listing need not reflect the same order of header fields that were entered.

23007 **Save Messages**

23008 *Synopsis*: `s[ave] [`*`file`*`]`
23009 `s[ave] [`*`msglist`*`] `*`file`*
23010 `S[ave] [`*`msglist`*`]`

23011 Save the specified messages in the file named by the path name *file*, or the **mbox** if the *file*
23012 argument is omitted. The file shall be created if it does not exist; otherwise, the messages shall be
23013 appended to the file. The message shall be put in the state *saved*, and shall behave as specified in
23014 the description of the *saved* state when the current mailbox is exited by the **quit** or **file**
23015 command.

23016 In the capitalized form, save the specified messages in a file whose name is derived from the
23017 author of the first message. The name of the file shall be taken to be the author's name with all
23018 network addressing stripped off. See also the **Copy**, **followup**, and **Followup** commands and
23019 **outfolder** variable.

23020 **Set Variables**

23021 *Synopsis*: `se[t] [`*`name`*`[=[`*`string`*`]] ...] [`*`name=number`*` ...] [no`*`name`*` ...]`

23022 Define one or more variables called *name*. The variable can be given a null, string, or numeric
23023 value. Quoting and backslash escapes can occur anywhere in *string*, as described previously, as
23024 if the *string* portion of the argument were the entire argument. The forms *name* and *name*= shall
23025 be equivalent to *name*="" for variables that take string values. The **set** command without
23026 arguments shall write a list of all defined variables and their values. The **no** *name* form shall be
23027 equivalent to **unset** *name*.

23028 **Invoke a Shell**

23029 *Synopsis*: `sh[ell]`

23030 Invoke an interactive command interpreter (see also *SHELL*).

23031 **Display Message Size**

23032 *Synopsis*: `si[ze] [`*`msglist`*`]`

23033 Write the size in bytes of each of the specified messages.

23034 **Read mailx Commands From a File**

23035 *Synopsis*: `so[urce] `*`file`*

23036 Read and execute commands from the file named by the path name *file* and return to command
23037 mode.

23038 **Display Beginning of Messages**

23039 *Synopsis*: `to[p] [`*`msglist`*`]`

23040 Write the top few lines of each of the specified messages. If the **toplines** variable is set, it is taken
23041 as the number of lines to write. The default shall be 5.

23042 **Touch Messages**

23043 *Synopsis*: `tou[ch] [`*`msglist`*`]`

23044 Touch the specified messages. If any message in *msglist* is not specifically deleted nor saved in a
23045 file, it shall be placed in the **mbox** upon normal termination. See **exit** and **quit**.

23046 **Delete Aliases**

23047 *Synopsis*: `una[lias] [`*`alias`*`]...`

23048 Delete the specified alias names. If a specified alias does not exist, the results are unspecified.

23049 **Undelete Messages**

23050 *Synopsis*: `u[ndelete] [`*`msglist`*`]`

23051 Change the state of the specified messages from deleted to read. If **autoprint** is set, the last
23052 message of those restored shall be written. If *msglist* is not specified, the message shall be
23053 selected as follows:

23054 • If there are any deleted messages that follow the current message, the first of these shall be
23055 chosen.

23056 • Otherwise, the last deleted message that also precedes the current message shall be chosen.

23057 **Unset Variables**

23058 *Synopsis*: `uns[et]` *`name`*`...`

23059 Cause the specified variables to be erased.

23060 **Edit Message with Full-Screen Editor**

23061 *Synopsis*: `v[isual] [`*`msglist`*`]`

23062 Edit the given messages with a screen editor. Each message shall be placed in a temporary file,
23063 and the utility named by the *VISUAL* variable shall be invoked to edit each file in sequence. The
23064 default editor shall be *vi*.

23065 The **visual** command does not modify the contents of those messages in the mailbox.

23066 **Write Messages to a File**

23067 *Synopsis*: `w[rite] [`*`msglist`*`]` *`file`*

23068 Write the given messages to the file specified by the path name *file*, minus the message header.
23069 Otherwise, it shall be equivalent to the **save** command.

23070 **Scroll Header Display**

23071 *Synopsis*: `z[+|-]`

23072 Scroll the header display forward (if '+' is specified or if no option is specified) or backward (if
23073 '-' is specified) one screenful. The number of headers written shall be set by the **screen**
23074 variable.

23075 **Invoke Shell Command**

23076 *Synopsis*: `!command`

23077 Invoke the command interpreter specified by *SHELL* with two arguments: **-c** and *command*.
23078 (See also *sh* **-c**.) If the **bang** variable is set, each unescaped occurrence of '!' in command shall
23079 be replaced with the command executed by the previous **!** command or **~!** command escape.

23080 **Null Command**

23081 *Synopsis*: `# comment`

23082 This null command (comment) shall be ignored by *mailx*.

23083 **Display Current Message Number**

23084 *Synopsis*: `=`

23085 Write the current message number.

23086 **Command Escapes in mailx**

23087 The following commands can be entered only from input mode, by beginning a line with the
23088 escape character (by default, tilde ('~')). See the **escape** variable description for changing this
23089 special character. The format for the commands shall be:

23090 `<ESC><command-char><separator>[<arguments>]`

23091 where the <*separator*> can be zero or more <blank> characters.

23092 In the following descriptions, the application shall ensure that the argument *command* (but not
23093 *mailx-command)* is a shell command string. Any string acceptable to the command interpreter
23094 specified by the *SHELL* variable when it is invoked as *SHELL* **-c** *command_string* shall be valid.
23095 The command can be presented as multiple arguments (that is, quoting is not required).

23096 Command escapes that are listed with *msglist* or *mailx-command* arguments are invalid in Send
23097 Mode and produce unspecified results.

23098 **~!** *command* Invoke the command interpreter specified by *SHELL* with two arguments: **-c** and
23099 *command*; and then return to input mode. If the **bang** variable is set, each
23100 unescaped occurrence of '!' in *command* shall be replaced with the command
23101 executed by the previous **!** command or **~!** command escape.

23102 **~.** Simulate end-of-file (terminate message input).

23103 **~:** *mailx-command*, **~_** *mailx-command*
23104 Perform the command-level request.

23105 **~?** Write a summary of command escapes.

23106 **~A** This shall be equivalent to **~i Sign**.

23107 **~a** This shall be equivalent to **~i sign**.

~b *name...* Add the *name*s to the blind carbon copy (**Bcc**) list.

~c *name...* Add the *name*s to the carbon copy (**Cc**) list.

~d Read in the dead-letter file. See *DEAD* for a description of this file.

~e Invoke the editor, as specified by the *EDITOR* environment variable, on the partial message.

~f [*msglist***]** Forward the specified messages. The specified messages shall be inserted into the current message without alteration. This command escape also shall insert message headers into the message with field selection affected by the **discard**, **ignore**, and **retain** commands.

~F [*msglist***]** This shall be the equivalent of the **~f** command escape, except that all headers shall be included in the message, regardless of previous **discard**, **ignore**, and **retain** commands.

~h If standard input is a terminal, prompt for a **Subject** line and the **To**, **Cc**, and **Bcc** lists. Other implementation-defined headers may also be presented for editing. If the field is written with an initial value, it can be edited as if it had just been typed.

~i *string* Insert the value of the named variable, followed by a <newline> character, into the text of the message. If the string is unset or null, the message shall not be changed.

~m [*msglist***]** Insert the specified messages into the message, prefixing non-empty lines with the string in the **indentprefix** variable. This command escape also shall insert message headers into the message, with field selection affected by the **discard**, **ignore**, and **retain** commands.

~M [*msglist***]** This shall be the equivalent of the **~m** command escape, except that all headers shall be included in the message, regardless of previous **discard**, **ignore**, and **retain** commands.

~p Write the message being entered. If the message is longer than **crt** lines (see **Internal Variables in mailx** (on page 2801)), the output shall be paginated as described for the *PAGER* variable.

~q Quit (see the **quit** command) from input mode by simulating an interrupt. If the body of the message is not empty, the partial message shall be saved in the dead-letter file. See *DEAD* for a description of this file.

"**~r** *file*, **~<** *file*, **~r** **!***command*, **~<** **!***command*"
Read in the file specified by the path name *file*. If the argument begins with an exclamation mark (′!′), the rest of the string shall be taken as an arbitrary system command; the command interpreter specified by *SHELL* shall be invoked with two arguments: **–c** and *command*. The standard output of *command* shall be inserted into the message.

~s *string* Set the subject line to *string*.

~t *name...* Add the given *name*s to the **To** list.

~v Invoke the full-screen editor, as specified by the *VISUAL* environment variable, on the partial message.

~w *file* Write the partial message, without the header, onto the file named by the path name *file*. The file shall be created or the message shall be appended to it if the file exists.

~x Exit as with **~q**, except the message shall not be saved in the dead-letter file.

~| *command* Pipe the body of the message through the given *command* by invoking the command interpreter specified by *SHELL* with two arguments: **–c** and *command*. If the *command* returns a successful exit status, the standard output of the command shall replace the message. Otherwise, the message shall remain unchanged. If the *command* fails, an error message giving the exit status shall be written.

EXIT STATUS

When the **–e** option is specified, the following exit values are returned:

0 Mail was found.

>0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0 Successful completion; note that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When in input mode (Receive Mode) or Send Mode:

- If an error is encountered processing a command escape (see **Command Escapes in mailx** (on page 2812)), a diagnostic message shall be written to standard error, and the message being composed may be modified, but this condition shall not prevent the message from being sent.
- Other errors shall prevent the sending of the message.

When in command mode:

- Default.

APPLICATION USAGE

Delivery of messages to remote systems requires the existence of communication paths to such systems. These need not exist.

Input lines are limited to {LINE_MAX} bytes, but mailers between systems may impose more severe line-length restrictions. This volume of IEEE Std. 1003.1-200x does not place any restrictions on the length of messages handled by *mailx*, and for delivery of local messages the only limitations should be the normal problems of available disk space for the target mail file. When sending messages to external machines, applications are advised to limit messages to less than 100 kilobytes because some mail gateways impose message-length restrictions.

The format of the system mailbox is intentionally unspecified. Not all systems implement system mailboxes as flat files, particularly with the advent of multimedia mail messages. Some system mailboxes may be multiple files, others records in a database. The internal format of the messages themselves are specified with the historical format from Version 7, but only after they have been saved in some file other than the system mailbox. This was done so that many historical applications expecting text-file mailboxes are not broken.

Some new formats for messages can be expected in the future, probably including binary data, bit maps, and various multimedia objects. As described here, *mailx* is not prohibited from handling such messages, but it must store them as text files in secondary mailboxes (unless some extension, such as a variable or command line option, is used to change the stored format). Its method of doing so is implementation-defined and might include translating the data into

text file-compatible or readable form or omitting certain portions of the message from the stored output.

The **discard** and **ignore** commands are not inverses of the **retain** command. The **retain** command discards all header-fields except those explicitly retained. The **discard** command keeps all header-fields except those explicitly discarded. If headers exist on the retained header list, **discard** and **ignore** commands are ignored.

EXAMPLES

None.

RATIONALE

The standard developers felt strongly that a method for applications to send messages to specific users was necessary. The obvious example is a batch utility, running non-interactively, that wishes to communicate errors or results to a user. However, the actual format, delivery mechanism, and method of reading the message are clearly beyond the scope of this volume of IEEE Std. 1003.1-200x.

The intent of this command is to provide a simple, portable interface for sending messages non-interactively. It merely defines a ''front-end'' to the historical mail system. It is suggested that implementations explicitly denote the sender and recipient in the body of the delivered message. Further specification of formats for either the message envelope or the message itself were deliberately not made, as the industry is in the midst of changing from the current standards to a more internationalized standard and it is probably incorrect, at this time, to require either one.

Implementations are encouraged to conform to the various delivery mechanisms described in the CCITT X.400 standards or to the equivalent Internet standards, described in Internet Request for Comment (RFC) documents RFC 819, RFC 822, RFC 920, RFC 921, and RFC 1123.

Many historical systems modified each body line that started with **From** by prefixing the `'F'` with `'>'`. It is unnecessary, but allowed, to do that when the string does not follow a blank line because it cannot be confused with the next header.

The *edit* and *visual* commands merely edit the specified messages in a temporary file. They do not modify the contents of those messages in the mailbox; such a capability could be added as an extension, such as by using different command names.

The restriction on a subject line being {LINE_MAX}–10 bytes is based on the historical format that consumes 10 bytes for **Subject:** and the trailing <newline>. Many historical mailers that a message may encounter on other systems are not able to handle lines that long, however.

Like the utilities *logger* and *lp*, *mailx* admittedly is difficult to test. This was not deemed sufficient justification to exclude this utility from this volume of IEEE Std. 1003.1-200x. It is also arguable that it is, in fact, testable, but that the tests themselves are not portable.

When *mailx* is being used by an application that wishes to receive the results as if none of the User Portability Utilities option features were supported, the *DEAD* environment variable must be set to **/dev/null**. Otherwise, it may be subject to the file creations described in *mailx* ASYNCHRONOUS EVENTS. Similarly, if the *MAILRC* environment variable is not set to **/dev/null**, historical versions of *mailx* and *Mail* read initialization commands from a file before processing begins. Since the initialization that a user specifies could alter the contents of messages an application is trying to send, such applications must set *MAILRC* to **/dev/null**.

The description of *LC_TIME* uses ''may affect'' because many historical implementations do not or cannot manipulate the date and time strings in the incoming mail headers. Some headers found in incoming mail do not have enough information to determine the timezone in which the mail originated, and, therefore, *mailx* cannot convert the date and time strings into the internal form that then is parsed by routines like *strftime*( ) that can take *LC_TIME* settings into account.

Changing all these times to a user-specified format is allowed, but not required.

The paginator selected when *PAGER* is null or unset is partially unspecified to allow the System V historical practice of using *pg* as the default. Bypassing the pagination function, such as by declaring that *cat* is the paginator, would not meet with the intended meaning of this description. However, any ''portable user'' would have to set *PAGER* explicitly to get his or her preferred paginator on all systems. The paginator choice was made partially unspecified, unlike the *VISUAL* editor choice (mandated to be *vi*) because most historical pagers follow a common theme of user input, whereas editors differ dramatically.

Options to specify addresses as **cc** (carbon copy) or **bcc** (blind carbon copy) were considered to be format details and were omitted.

A zero exit status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*. The reliability of the delivery mechanism is unspecified and is an appropriate marketing distinction between systems.

In order to conform to the Utility Syntax Guidelines, a solution was required to the optional *file* option-argument to **–f**. By making *file* an operand, the guidelines are satisfied and users remain portable. However, it does force implementations to support usage such as:

```
mailx –fin mymail.box
```

The **no** *name* method of unsetting variables is not present in all historical systems, but it is in System V and provides a logical set of commands corresponding to the format of the display of options from the *mailx set* command without arguments.

The **ask** and **asksub** variables are the names selected by BSD and System V, respectively, for the same feature. They are synonyms in this volume of IEEE Std. 1003.1-200x.

The *mailx echo* command was not documented in the BSD version and has been omitted here because it is not obviously useful for interactive users.

The default prompt on the System V *mailx* is a question mark, on BSD *Mail* an ampersand. Since this volume of IEEE Std. 1003.1-200x chose the *mailx* name, it kept the System V default, assuming that BSD users would not have difficulty with this minor incompatibility (that they can override).

The meanings of **r** and **R** are reversed between System V *mailx* and SunOS *Mail*. Once again, since this volume of IEEE Std. 1003.1-200x chose the *mailx* name, it kept the System V default, but allows the SunOS user to achieve the desired results using **flipr**, an internal variable in System V *mailx*, although it has not been documented in the SVID

The **indentprefix** variable, the **retain** and **unalias** commands, and the **~F** and **~M** command escapes were adopted from 4.3 BSD *Mail*.

The **version** command was not included because no sufficiently general specification of the version information could be devised that would still be useful to a portable user. This command name should be used by suppliers who wish to provide version information about the *mailx* command.

The ''implementation-specific (unspecified) system start-up file'' historically has been named **/etc/mailx.rc**, but this specific name and location are not required.

The intent of the wording for the **next** command is that if any command has already displayed the current message it should display a following message, but, otherwise, it should display the current message. Consider the command sequence:

```
next 3
delete 3
```

```
next
```

where the **autoprint** option was not set. The normative text specifies that the second **next** command should display a message following the third message, because even though the current message has not been displayed since it was set by the **delete** command, it has been displayed since the current message was anything other than message number 3. This does not always match historical practice in some implementations, where the command file address followed by **next** (or the default command) would skip the message for which the user had searched.

FUTURE DIRECTIONS

None.

SEE ALSO

ed, *ls*, *more*, *vi*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

This utility is now mandatory; it is optional in Issue 3.

Issue 5

The description of the EDITOR environment variable is changed to indicate that *ed* is the default editor if this variable is not set. In previous issues, this default was not stated explicitly at this point but was implied further down in the text.

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–F** option is added.
- The **allnet**, **debug**, and **sendwait** internal variables are added.
- The **C**, **ec**, **fo**, **F**, and **S** *mailx* commands are added.

In the DESCRIPTION and ENVIRONMENT VARIABLES sections, text stating ‘‘*HOME* directory’’ is replaced by ‘‘directory referred to by the *HOME* environment variable’’.

The *mailx* utility is aligned with the IEEE P1003.2b draft standard, which included various clarifications to resolve IEEE PASC Interpretations submitted for the ISO POSIX-2: 1993 standard. In particular, the changes here address IEEE PASC Interpretations 1003.2 #10, #11, #103, #106, #108, #114, #115, #122, and #129.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

make — maintain, update, and regenerate groups of programs (**DEVELOPMENT**)

SYNOPSIS

SD

```
make [–einpqrst][–f makefile]...[ –k| –S][macro=value]...
    [target_name...]
```

DESCRIPTION

The *make* utility can be used as a part of software development to update files that are derived from other files. A typical case is one where object files are derived from the corresponding source files. The *make* utility examines time relationships and updates those derived files (called targets) that have modified times earlier than the modified times of the files (called prerequisites) from which they are derived. A description file (makefile) contains a description of the relationships between files, and the commands that need to be executed to update the targets to reflect changes in their prerequisites. Each specification, or rule, shall consist of a target, optional prerequisites, and optional commands to be executed when a prerequisite is newer than the target. There are two types of rule:

1. *Inference rules*, which have one target name with at least one period (`'.'`) and no slash (`'/'`)
2. *Target rules*, which can have more than one target name

In addition, *make* shall have a collection of built-in macros and inference rules that infer prerequisite relationships to simplify maintenance of programs.

To receive exactly the behavior described in this section, the user shall ensure that a portable makefile:

- Includes the special target **.POSIX**
- Omits any special target reserved for implementations (a leading period followed by uppercase letters) that has not been specified by this section

The behavior of *make* is unspecified if either or both of these conditions are not met.

OPTIONS

The *make* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–e Cause environment variables, including those with null values, to override macro assignments within makefiles.

–f *makefile* Specify a different makefile. The argument *makefile* is a path name of a description file, which is also referred to as the *makefile*. A path name of `'–'` shall denote the standard input. There can be multiple instances of this option, and they shall be processed in the order specified. The effect of specifying the same option-argument more than once is unspecified.

–i Ignore error codes returned by invoked commands. This mode is the same as if the special target **.IGNORE** were specified without prerequisites.

–k Continue to update other targets that do not depend on the current target if a non-ignored error occurs while executing the commands to bring a target up-to-date.

–n Write commands that would be executed on standard output, but do not execute them. However, lines with a plus sign (`'+'`) prefix shall be executed. In this mode,

lines with an at sign ('@') character prefix shall be written to standard output.

−p Write to standard output the complete set of macro definitions and target descriptions. The output format is unspecified.

−q Return a zero exit value if the target file is up-to-date; otherwise, return an exit value of 1. Targets shall not be updated if this option is specified. However, a makefile command line (associated with the targets) with a plus sign ('+') prefix shall be executed.

−r Clear the suffix list and does not use the built-in rules.

−S Terminate *make* if an error occurs while executing the commands to bring a target up-to-date. This shall be the default and the opposite of **−k**.

−s Do not write makefile command lines or touch messages (see **−t**) to standard output before executing. This mode shall be the same as if the special target **.SILENT** were specified without prerequisites.

−t Update the modification time of each target as though a *touch target* had been executed. Targets that have prerequisites but no commands (see **Target Rules** (on page 2822)), or that are already up-to-date, shall not be touched in this manner. Write messages to standard output for each target file indicating the name of the file and that it was touched. Normally, the makefile command lines associated with each target are not executed. However, a command line with a plus sign ('+') prefix shall be executed.

Any options specified in the *MAKEFLAGS* environment variable shall be evaluated before any options specified on the *make* utility command line. If the **−k** and **−S** options are both specified on the *make* utility command line or by the *MAKEFLAGS* environment variable, the last option specified shall take precedence. If the **−f** or **−p** options appear in the *MAKEFLAGS* environment variable, the result is undefined.

OPERANDS

The following operands shall be supported:

target_name Target names, as defined in the EXTENDED DESCRIPTION section. If no target is specified, while *make* is processing the makefiles, the first target that *make* encounters that is not a special target or an inference rule shall be used.

macro=value Macro definitions, as defined in **Macros** (on page 2824).

If the *target_name* and *macro=value* operands are intermixed on the *make* utility command line, the results are unspecified.

STDIN

The standard input shall be used only if the *makefile* option-argument is '−'. See the INPUT FILES section.

INPUT FILES

The input file, otherwise known as the makefile, is a text file containing rules, macro definitions, and comments.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *make*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had

23411 been defined.

23412 *LC_ALL* If set to a non-empty string value, override the values of all the other
23413 internationalization variables.

23414 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
23415 characters (for example, single-byte as opposed to multi-byte characters in
23416 arguments and input files).

23417 *LC_MESSAGES*
23418 Determine the locale that should be used to affect the format and contents of
23419 diagnostic messages written to standard error.

23420 *MAKEFLAGS*
23421 This variable shall be interpreted as a character string representing a series of
23422 option characters to be used as the default options. The implementation shall
23423 accept both of the following formats (but need not accept them when intermixed):

23424 • The characters are option letters without the leading hyphens or <blank>
23425 character separation used on a *make* utility command line.

23426 • The characters are formatted in a manner similar to a portion of the *make* utility
23427 command line: options are preceded by hyphens and <blank> character-
23428 separated as described in the Base Definitions volume of IEEE Std. 1003.1-200x,
23429 Section 12.2, Utility Syntax Guidelines. The *macro=value* macro definition
23430 operands can also be included. The difference between the contents of
23431 *MAKEFLAGS* and the *make* utility command line is that the contents of the
23432 variable shall not be subjected to the word expansions (see Section 2.6 (on page
23433 2244)) associated with parsing the command line values.

23434 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

23435 XSI *PROJECTDIR*
23436 Provide a directory to be used to search for SCCS files not found in the current
23437 directory. In all of the following cases, the search for SCCS files is made in the
23438 directory **SCCS** in the identified directory. If the value of *PROJECTDIR* begins
23439 with a slash, it shall be considered an absolute path name; otherwise, the value of
23440 *PROJECTDIR* is treated as a user name and that user's initial working directory
23441 shall be examined for a subdirectory **src** or **source**. If such a directory is found, it
23442 shall be used. Otherwise, the value is used as a relative path name.

23443 If *PROJECTDIR* is not set or has a null value, the search for SCCS files shall be
23444 made in the directory **SCCS** in the current directory.

23445 The setting of *PROJECTDIR* affects all files listed in the remainder of this utility
23446 description for files with a component named **SCCS**.

23447 The value of the *SHELL* environment variable shall not be used as a macro and shall not be
23448 modified by defining the **SHELL** macro in a makefile or on the command line. All other
23449 environment variables, including those with null values, shall be used as macros, as defined in
23450 **Macros** (on page 2824).

23451 **ASYNCHRONOUS EVENTS**

23452 If not already ignored, *make* shall trap SIGHUP, SIGTERM, SIGINT, and SIGQUIT and remove
23453 the current target unless the target is a directory or the target is a prerequisite of the special
23454 target **.PRECIOUS** or unless one of the **−n**, **−p**, or **−q** options was specified. Any targets removed
23455 in this manner shall be reported in diagnostic messages of unspecified format, written to
23456 standard error. After this cleanup process, if any, *make* shall take the standard action for all other

signals.

STDOUT

The *make* utility shall write all commands to be executed to standard output unless the **–s** option was specified, the command is prefixed with an at sign, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites. If *make* is invoked without any work needing to be done, it shall write a message to standard output indicating that no action was taken. If the **–t** option is present and a file is touched, *make* shall write to standard output a message of unspecified format indicating that the file was touched, including the file name of the file.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

Files can be created when the **–t** option is present. Additional files can also be created by the utilities invoked by *make*.

EXTENDED DESCRIPTION

The *make* utility attempts to perform the actions required to ensure that the specified targets are up-to-date. A target is considered out-of-date if it is older than any of its prerequisites or if it does not exist. The *make* utility shall treat all prerequisites as targets themselves and recursively ensure that they are up-to-date, processing them in the order in which they appear in the rule. The *make* utility shall use the modification times of files to determine whether the corresponding targets are out-of-date.

After *make* has ensured that all of the prerequisites of a target are up-to-date and if the target is out-of-date, the commands associated with the target entry shall be executed. If there are no commands listed for the target, the target shall be treated as up-to-date.

Makefile Syntax

A makefile can contain rules, macro definitions (see **Macros** (on page 2824)), and comments. There are two kinds of rules: *inference rules* and *target rules*. The *make* utility shall contain a set of built-in inference rules. If the **–r** option is present, the built-in rules shall not be used and the suffix list shall be cleared. Additional rules of both types can be specified in a makefile. If a rule is defined more than once, the value of the rule shall be that of the last one specified. Macros can also be defined more than once, and the value of the macro is specified in **Macros** (on page 2824). Comments start with a number sign (`'#'`) and continue until an unescaped <newline> character is reached.

By default, the following files shall be tried in sequence: **./makefile** and **./Makefile**. If neither **./makefile** or **./Makefile** are found, other implementation-defined files may also be tried. On XSI-conformant systems, the additional files **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile** shall also be tried.

The **–f** option shall direct *make* to ignore any of these default files and use the specified argument as a makefile instead. If the `'–'` argument is specified, standard input shall be used.

The term *makefile* is used to refer to any rules provided by the user, whether in **./makefile** or its variants, or specified by the **–f** option.

The rules in makefiles shall consist of the following types of lines: target rules, including special targets (see **Target Rules** (on page 2822)), inference rules (see **Inference Rules** (on page 2825)), macro definitions (see **Macros** (on page 2824)), empty lines, and comments.

When an escaped <newline> (one preceded by a backslash) is found anywhere in the makefile except in a command line, it shall be replaced, along with any leading white space on the

following line, with a single <space>. When an escaped <newline> is found in a command line in a makefile, the command line shall contain the backslash, the <newline>, and the next line, except that the first character of the next line shall not be included if it is a <tab>.

Makefile Execution

Makefile command lines shall be processed one at a time by writing the makefile command line to the standard output (unless one of the conditions listed under '@' suppresses the writing) and executing the command(s) in the line. A <tab> character may precede the command to standard output. Command execution shall be as if the makefile command line were the argument to the *system*( ) function. The environment for the command being executed shall contain all of the variables in the environment of *make*.

By default, when *make* receives a non-zero status from the execution of a command, it terminates with an error message to standard error.

Makefile command lines can have one or more of the following prefixes: a hyphen ('–'), an at sign ('@'), or a plus sign ('+'). These modify the way in which *make* processes the command. When a command is written to standard output, the prefix shall not be included in the output.

– If the command prefix contains a hyphen, or the **–i** option is present, or the special target **.IGNORE** has either the current target as a prerequisite or has no prerequisites, any error found while executing the command shall be ignored.

@ If the command prefix contains an at sign and the *make* utility command line **–n** option is not specified, or the **–s** option is present, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites, the command shall not be written to standard output before it is executed.

\+ If the command prefix contains a plus sign, this indicates a makefile command line that shall be executed even if **–n**, **–q**, or **–t** is specified.

Target Rules

Target rules are formatted as follows:

```
target [target...]: [prerequisite...][;command]
[<tab>command
<tab>command
...]
line that does not begin with <tab>
```

Target entries are specified by a <blank> character-separated, non-null list of targets, then a colon, then a <blank> character-separated, possibly empty list of prerequisites. Text following a semicolon, if any, and all following lines that begin with a <tab> character, are makefile command lines to be executed to update the target. The first non-empty line that does not begin with a <tab> character or '#' shall begin a new entry. An empty or blank line, or a line beginning with '#', may begin a new entry.

Applications shall select target names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set). Implementations may allow other characters in target names as extensions. The interpretation of targets containing the characters '%' and '"' is implementation-defined.

A target that has prerequisites, but does not have any commands, can be used to add to the prerequisite list for that target. Only one target rule for any given target can contain commands.

Lines that begin with one of the following are called *special targets* and control the operation of *make*:

.DEFAULT If the makefile uses this special target, the application shall ensure that it is specified with commands, but without prerequisites. The commands shall be used by *make* if there are no other rules available to build a target.

.IGNORE Prerequisites of this special target are targets themselves; this shall cause errors from commands associated with them to be ignored in the same manner as specified by the **–i** option. Subsequent occurrences of **.IGNORE** shall add to the list of targets ignoring command errors. If no prerequisites are specified, *make* shall behave as if the **–i** option had been specified and errors from all commands associated with all targets shall be ignored.

.POSIX The application shall ensure that this special target is specified without prerequisites or commands. If it appears as the first non-comment line in the makefile, *make* shall process the makefile as specified by this section; otherwise, the behavior of *make* is unspecified.

.PRECIOUS Prerequisites of this special target shall not be removed if *make* receives one of the asynchronous events explicitly described in the ASYNCHRONOUS EVENTS section. Subsequent occurrences of **.PRECIOUS** shall add to the list of precious files. If no prerequisites are specified, all targets in the makefile shall be treated as if specified with **.PRECIOUS**.

XSI **.SCCS_GET** The application shall ensure that this special target is specified without prerequisites. If this special target is included in a makefile, the commands specified with this target shall replace the default commands associated with this special target (see **Default Rules** (on page 2828)). The commands specified with this target are used to get all SCCS files that are not found in the current directory.

When source files are named in a dependency list, *make* treats them just like any other target. Because the source file is presumed to be present in the directory, there is no need to add an entry for it to the makefile. When a target has no dependencies, but is present in the directory, *make* assumes that that file is up-to-date. If, however, an SCCS file named **SCCS/s.***source_file* is found for a target *source_file*, *make* does some additional checking to assure that the target is up-to-date. If the target is missing, or if the SCCS file is newer, *make* automatically issues the commands specified for the **.SCCS_GET** special target to retrieve the most recent version. However, if the target is writable by anyone, *make* does not retrieve a new version.

.SILENT Prerequisites of this special target are targets themselves; this shall cause commands associated with them to not be written to the standard output before they are executed. Subsequent occurrences of **.SILENT** shall add to the list of targets with silent commands. If no prerequisites are specified, *make* shall behave as if the **–s** option had been specified and no commands or touch messages associated with any target shall be written to standard output.

.SUFFIXES Prerequisites of **.SUFFIXES** shall be appended to the list of known suffixes and are used in conjunction with the inference rules (see **Inference Rules** (on page 2825)). If **.SUFFIXES** does not have any prerequisites, the list of known suffixes shall be cleared.

The special targets **.IGNORE**, **.POSIX**, **.PRECIOUS**, **.SILENT**, and **.SUFFIXES** shall be specified without commands.

Targets with names consisting of a leading period followed by the uppercase letters "POSIX" and then any other characters are reserved for future standardization. Targets with names consisting of a leading period followed by one or more uppercase letters are reserved for implementation extensions.

Macros

Macro definitions are in the form:

string1 = [*string2*]

The macro named *string1* is defined as having the value of *string2*, where *string2* is defined as all characters, if any, after the equal sign, up to a comment character ('#') or an unescaped <newline> character. Any <blank> characters immediately before or after the equal sign shall be ignored.

Applications shall select macro names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set). A macro name shall not contain an equals sign. Implementations may allow other characters in macro names as extensions.

Macros can appear anywhere in the makefile. **$**(*string1*) or **$**{*string1*} shall be replaced by *string2*, as follows:

- Macros in target lines shall be evaluated when the target line is read.
- Macros in makefile command lines shall be evaluated when the command is executed.
- Macros in the string before the equals sign in a macro definition shall be evaluated when the macro assignment is made.
- Macros after the equals sign in a macro definition shall not be evaluated until the defined macro is used in a rule or command, or before the equals sign in a macro definition.

The parentheses or braces are optional if *string1* is a single character. The macro **$$** shall be replaced by the single character '$'.

The forms **$**(*string1***[:***subst1***=[***subst2***]]**) or **$**{*string1***[:***subst1***=[***subst2***]]**} can be used to replace all occurrences of *subst1* with *subst2* when the macro substitution is performed. The *subst1* to be replaced shall be recognized when it is a suffix at the end of a word in *string1* (where a *word*, in this context, is defined to be a string delimited by the beginning of the line, a <blank> or <newline> character).

Macro definitions shall be taken from the following sources, in the following logical order, before the makefile(s) are read.

1. Macros specified on the *make* utility command line, in the order specified on the command line. It is unspecified whether the internal macros defined in **Internal Macros** (on page 2826) are accepted from this source.
2. Macros defined by the *MAKEFLAGS* environment variable, in the order specified in the environment variable. It is unspecified whether the internal macros defined in **Internal Macros** (on page 2826) are accepted from this source.
3. The contents of the environment, excluding the *MAKEFLAGS* and *SHELL* variables and including the variables with null values.
4. Macros defined in the inference rules built into *make*.

Macro definitions from these sources shall not override macro definitions from a lower-numbered source. Macro definitions from a single source (for example, the *make* utility command line, the *MAKEFLAGS* environment variable, or the other environment variables) shall override previous macro definitions from the same source.

Macros defined in the makefile(s) shall override macro definitions that occur before them in the makefile(s) and macro definitions from source 4. If the **−e** option is not specified, macros defined in the makefile(s) shall override macro definitions from source 3. Macros defined in the makefile(s) shall not override macro definitions from source 1 or source 2.

Before the makefile(s) are read, all of the *make* utility command line options (except **−f** and **−p**) and *make* utility command line macro definitions (except any for the *MAKEFLAGS* macro), not already included in the *MAKEFLAGS* macro, shall be added to the *MAKEFLAGS* macro. Other implementation-defined options and macros may also be added to the *MAKEFLAGS* macro. If this modifies the value of the *MAKEFLAGS* macro, or, if the *MAKEFLAGS* macro is modified at any subsequent time, the *MAKEFLAGS* environment variable shall be modified to match the new value of the *MAKEFLAGS* macro.

Before the makefile(s) are read, all of the *make* utility command line macro definitions (except the *MAKEFLAGS* macro or the *SHELL* macro) shall be added to the environment of *make*. Other implementation-defined variables may also be added to the environment of *make*.

The **SHELL** macro shall be treated specially. It shall be provided by *make* and set to the path name of the shell command language interpreter (see *sh* (on page 3060)). The *SHELL* environment variable shall not affect the value of the **SHELL** macro. If **SHELL** is defined in the makefile or is specified on the command line, it shall replace the original value of the **SHELL** macro, but shall not affect the *SHELL* environment variable. Other effects of defining **SHELL** in the makefile or on the command line are implementation-defined.

Inference Rules

Inference rules are formatted as follows:

```
target:
<tab>command
[<tab>command]
...
```

line that does not begin with <tab> *or #*

The application shall ensure that the *target* portion is a valid target name (see **Target Rules** (on page 2822)) of the form **.s2** or **.s1.s2** (where **.s1** and **.s2** are suffixes that have been given as prerequisites of the **.SUFFIXES** special target and *s1* and *s2* do not contain any slashes or periods.) If there is only one period in the target, it is a single-suffix inference rule. Targets with two periods are double-suffix inference rules. Inference rules can have only one target before the colon.

The application shall ensure that the makefile does not specify prerequisites for inference rules; no characters other than white space shall follow the colon in the first line, except when creating the *empty rule*, described below. Prerequisites are inferred, as described below.

Inference rules can be redefined. A target that matches an existing inference rule shall overwrite the old inference rule. An empty rule can be created with a command consisting of simply a semicolon (that is, the rule still exists and is found during inference rule search, but since it is empty, execution has no effect). The empty rule also can be formatted as follows:

```
rule: ;
```

where zero or more <blank> characters separate the colon and semicolon.

The *make* utility uses the suffixes of targets and their prerequisites to infer how a target can be made up-to-date. A list of inference rules defines the commands to be executed. By default, *make* contains a built-in set of inference rules. Additional rules can be specified in the makefile.

The special target **.SUFFIXES** contains as its prerequisites a list of suffixes that shall be used by the inference rules. The order in which the suffixes are specified defines the order in which the inference rules for the suffixes are used. New suffixes shall be appended to the current list by specifying a **.SUFFIXES** special target in the makefile. A **.SUFFIXES** target with no prerequisites shall clear the list of suffixes. An empty **.SUFFIXES** target followed by a new **.SUFFIXES** list is required to change the order of the suffixes.

Normally, the user would provide an inference rule for each suffix. The inference rule to update a target with a suffix **.s1** from a prerequisite with a suffix **.s2** is specified as a target **.s2.s1**. The internal macros provide the means to specify general inference rules (see **Internal Macros**).

When no target rule is found to update a target, the inference rules shall be checked. The suffix of the target (**.s1**) to be built is compared to the list of suffixes specified by the **.SUFFIXES** special targets. If the **.s1** suffix is found in **.SUFFIXES**, the inference rules shall be searched in the order defined for the first **.s2.s1** rule whose prerequisite file (**$*.s2**) exists. If the target is out-of-date with respect to this prerequisite, the commands for that inference rule shall be executed.

If the target to be built does not contain a suffix and there is no rule for the target, the single suffix inference rules shall be checked. The single-suffix inference rules define how to build a target if a file is found with a name that matches the target name with one of the single suffixes appended. A rule with one suffix **.s2** is the definition of how to build *target* from **target.s2**. The other suffix (**.s1**) is treated as null.

XSI A tilde (′~′) in the above rules refers to an SCCS file in the current directory. Thus, the rule **.c~.o** would transform an SCCS C-language source file into an object file (**.o**). Because the **s.** of the SCCS files is a prefix, it is incompatible with *make*'s suffix point of view. Hence, the ′~′ is a way of changing any file reference into an SCCS file reference.

Libraries

If a target or prerequisite contains parentheses, it shall be treated as a member of an archive library. For the *lib*(*member***.o**) expression *lib* refers to the name of the archive library and *member***.o** to the member name. The application shall ensure that the member is an object file with the **.o** suffix. The modification time of the expression is the modification time for the member as kept in the archive library; see *ar* (on page 2348). The **.a** suffix refers to an archive library. The **.s2.a** rule is used to update a member in the library from a file with a suffix **.s2**.

Internal Macros

The *make* utility shall maintain five internal macros that can be used in target and inference rules. In order to clearly define the meaning of these macros, some clarification of the terms *target rule*, *inference rule*, *target*, and *prerequisite* is necessary.

Target rules are specified by the user in a makefile for a particular target. Inference rules are user-specified or *make*-specified rules for a particular class of target name. Explicit prerequisites are those prerequisites specified in a makefile on target lines. Implicit prerequisites are those prerequisites that are generated when inference rules are used. Inference rules are applied to implicit prerequisites or to explicit prerequisites that do not have target rules defined for them in the makefile. Target rules are applied to targets specified in the makefile.

Before any target in the makefile is updated, each of its prerequisites (both explicit and implicit) shall be updated. This shall be accomplished by recursively processing each prerequisite. Upon recursion, each prerequisite shall become a target itself. Its prerequisites in turn shall be processed recursively until a target is found that has no prerequisites, at which point the recursion stops. The recursion then shall back up, updating each target as it goes.

In the definitions that follow, the word *target* refers to one of:

- A target specified in the makefile
- An explicit prerequisite specified in the makefile that becomes the target when *make* processes it during recursion
- An implicit prerequisite that becomes a target when *make* processes it during recursion

In the definitions that follow, the word *prerequisite* refers to one of the following:

- An explicit prerequisite specified in the makefile for a particular target
- An implicit prerequisite generated as a result of locating an appropriate inference rule and corresponding file that matches the suffix of the target

The five internal macros are:

$@** The **$@ shall evaluate to the full target name of the current target, or the archive file name part of a library archive target. It shall be evaluated for both target and inference rules.

For example, in the **.c.a** inference rule, **$@** represents the out-of-date **.a** file to be built. Similarly, in a makefile target rule to build **lib.a** from **file.c**, **$@** represents the out-of-date **lib.a**.

$% The **$%** macro shall be evaluated only when the current target is an archive library member of the form *libname*(*member*.**o**). In these cases, **$@** shall evaluate to *libname* and **$%** shall evaluates to *member*.**o**. The **$%** macro shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build **lib.a**(**file.o**), **$%** represents **file.o**, as opposed to **$@**, which represents **lib.a**.

$?** The **$? macro shall evaluate to the list of prerequisites that are newer than the current target. It shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build *prog* from **file1.o**, **file2.o**, and **file3.o**, and where *prog* is not out of date with respect to **file1.o**, but is out of date with respect to **file2.o** and **file3.o**, **$?** represents **file2.o** and **file3.o**.

$<** In an inference rule, the **$< macro shall evaluate to the file name whose existence allowed the inference rule to be chosen for the target. In the **.DEFAULT** rule, the **$<** macro shall evaluate to the current target name. The meaning of the **$<** macro is otherwise unspecified.

For example, in the **.c.a** inference rule, **$<** represents the prerequisite **.c** file.

$* The **$*** macro shall evaluate to the current target name with its suffix deleted. It shall be evaluated at least for inference rules.

For example, in the **.c.a** inference rule, **$*.o** represents the out-of-date **.o** file that corresponds to the prerequisite **.c** file.

Each of the internal macros has an alternative form. When an uppercase 'D' or 'F' is appended to any of the macros, the meaning is changed to the *directory part* for 'D' and *file name part* for

23768 'F'. The directory part is the path prefix of the file without a trailing slash; for the current
23769 directory, the directory part is '.'. When the **$?** macro contains more than one prerequisite file
23770 name, the **$(?D)** and **$(?F)** (or **${?D}** and **${?F}**) macros expand to a list of directory name parts
23771 and file name parts respectively.

23772 For the target *lib*(*member***.o**) and the **s2.a** rule, the internal macros are defined as:

23773 $< *member***.s2**

23774 $* *member*

23775 $@ *lib*

23776 $? *member***.s2**

23777 $% *member***.o**

23778 **Default Rules**

23779 The default rules for *make* shall achieve results that are the same as if the following were used.
23780 Implementations that do not support the C-Language Development Utilities option may omit
23781 **CC**, **CFLAGS**, **YACC**, **YFLAGS**, **LEX**, **LFLAGS**, **LDFLAGS**, and the **.c**, **.y**, and **.l** inference rules.
23782 Implementations that do not support FORTRAN may omit **FC**, **FFLAGS**, and the **.f** inference
23783 rules. Implementations may provide additional macros and rules.

23784 *SPECIAL TARGETS*

23785 XSI
```
.SCCS_GET: sccs $(SCCSFLAGS) get $(SCCSGETFLAGS) $@
```
23786

23787 XSI
```
.SUFFIXES: .o .c .y .l .a .sh .f .c~ .y~ .l~ .sh~ .f~
```

23788 *MACROS*

```
MAKE=make
AR=ar

YACC=yacc
YFLAGS=
LEX=lex
LFLAGS=
LDFLAGS=
CC=c99
CFLAGS=-O
FC=fort77
FFLAGS=-O 1
```
23801 XSI
```
GET=get
GFLAGS=
SCCSFLAGS=
SCCSGETFLAGS=-s
```
23805

23806 *SINGLE SUFFIX RULES*

```
.c:
    $(CC) $(CFLAGS) $(LDFLAGS) -o $@ $<
.f:
    $(FC) $(FFLAGS) $(LDFLAGS) -o $@ $<
```

```
.sh:
    cp $< $@
    chmod a+x $@
```

XSI
```
.c~:
    $(GET) $(GFLAGS) -p $< > $*.c
    $(CC) $(CFLAGS) $(LDFLAGS) -o $@ $*.c
```

```
.f~:
    $(GET) $(GFLAGS) -p $< > $*.f
    $(FC) $(FFLAGS) $(LDFLAGS) -o $@ $*.f
```

```
.sh~:
    $(GET) $(GFLAGS) -p $< > $*.sh
    cp $*.sh $@
    chmod a+x $@
```

DOUBLE SUFFIX RULES

```
.c.o:
    $(CC) $(CFLAGS) -c $<
```

```
.f.o:
    $(FC) $(FFLAGS) -c $<
```

```
.y.o:
    $(YACC) $(YFLAGS) $<
    $(CC) $(CFLAGS) -c y.tab.c
    rm -f y.tab.c
    mv y.tab.o $@
```

```
.l.o:
    $(LEX) $(LFLAGS) $<
    $(CC) $(CFLAGS) -c lex.yy.c
    rm -f lex.yy.c
    mv lex.yy.o $@
```

```
.y.c:
    $(YACC) $(YFLAGS) $<
    mv y.tab.c $@
```

```
.l.c:
    $(LEX) $(LFLAGS) $<
    mv lex.yy.c $@
```

XSI
```
.c~.o:
    $(GET) $(GFLAGS) -p $< > $*.c
    $(CC) $(CFLAGS) -c $*.c
```

```
.f~.o:
    $(GET) $(GFLAGS) -p $< > $*.f
    $(FC) $(FFLAGS) -c $*.f
```

```
.y~.o:
    $(GET) $(GFLAGS) -p $< > $*.y
    $(YACC) $(YFLAGS) $*.y
    $(CC) $(CFLAGS) -c y.tab.c
    rm -f y.tab.c
```

```
23857        mv y.tab.o $@
23858    .l~.o:
23859        $(GET) $(GFLAGS) –p $< > $*.l
23860        $(LEX) $(LFLAGS) $*.l
23861        $(CC) $(CFLAGS) –c lex.yy.c
23862        rm –f lex.yy.c
23863        mv lex.yy.o $@
23864    .y~.c:
23865        $(GET) $(GFLAGS) –p $< > $*.y
23866        $(YACC) $(YFLAGS) $*.y
23867        mv y.tab.c $@
23868    .l~.c:
23869        $(GET) $(GFLAGS) –p $< > $*.l
23870        $(LEX) $(LFLAGS) $*.l
23871        mv lex.yy.c $@
23872
23873    .c.a:
23874        $(CC) –c $(CFLAGS) $<
23875        $(AR) $(ARFLAGS) $@ $*.o
23876        rm –f $*.o
23877    .f.a:
23878        $(FC) –c $(FFLAGS) $<
23879        $(AR) $(ARFLAGS) $@ $*.o
23880        rm –f $*.o
```

23881 **EXIT STATUS**

23882 When the **–q** option is specified, the *make* utility shall exit with one of the following values:

23883 0 Successful completion.

23884 1 The target was not up-to-date.

23885 >1 An error occurred.

23886 When the **–q** option is not specified, the *make* utility shall exit with one of the following values:

23887 0 Successful completion.

23888 >0 An error occurred.

23889 **CONSEQUENCES OF ERRORS**

23890 Default.

23891 **APPLICATION USAGE**

23892 If there is a source file (such as **./source.c**) and there are two SCCS files corresponding to it
23893 (**./s.source.c** and **./SCCS/s.source.c**), on XSI-conformant systems *make* uses the SCCS file in the
23894 current directory. However, users are advised to use the underlying SCCS utilities (*admin*, *delta*,
23895 *get*, and so on) or the *sccs* utility for all source files in a given directory. If both forms are used for
23896 a given source file, future developers are very likely to be confused.

23897 It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to
23898 guarantee that they are not affected by local extensions.

23899 The **–k** and **–S** options are both present so that the relationship between the command line, the
23900 *MAKEFLAGS* variable, and the makefile can be controlled precisely. If the **k** flag is passed in

23901 *MAKEFLAGS* and a command is of the form:

23902 `$(MAKE) –S foo`

23903 then the default behavior is restored for the child *make*.

23904 When the **–n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive
23905 *make* **–n** *target* to be used to see all of the action that would be taken to update *target*.

23906 Because of widespread historical practice, interpreting a `'#'` number sign inside a variable as
23907 the start of a comment has the unfortunate side effect of making it impossible to place a number
23908 sign in a variable, thus forbidding something like:

23909 `CFLAGS = "–D COMMENT_CHAR='#'"`

23910 Many historical *make* utilities stop chaining together inference rules when an intermediate target
23911 is nonexistent. For example, it might be possible for a *make* to determine that both **.y.c** and **.c.o**
23912 could be used to convert a **.y** to a **.o**. Instead, in this case, *make* requires the use of a **.y.o** rule.

23913 The best way to provide portable makefiles is to include all of the rules needed in the makefile
23914 itself. The rules provided use only features provided by other parts of this volume of
23915 IEEE Std. 1003.1-200x. The default rules include rules for optional commands in this volume of
23916 IEEE Std. 1003.1-200x. Only rules pertaining to commands that are provided are needed in an
23917 implementation's default set.

23918 Macros used within other macros are evaluated when the new macro is used rather than when
23919 the new macro is defined. Therefore:

23920 `MACRO = value1`
23921 `NEW   = $(MACRO)`
23922 `MACRO = value2`

23923 `target:`
23924 `    echo $(NEW)`

23925 would produce *value2* and not *value1* since **NEW** was not expanded until it was needed in the
23926 *echo* command line.

23927 Some historical applications have been known to intermix *target_name* and *macro=name* operands
23928 on the command line, expecting that all of the macros are processed before any of the targets are
23929 dealt with. Portable applications do not do this, although some backward compatibility support
23930 may be included in some implementations.

23931 The following characters in file names may give trouble: `'='`, `':'`, `'''`, `'''`, and `'@'`. For
23932 inference rules, the description of **$<** and **$?** seem similar. However, an example shows the
23933 minor difference. In a makefile containing:

23934 `foo.o: foo.h`

23935 if **foo.h** is newer than **foo.o**, yet **foo.c** is older than **foo.o**, the built-in rule to make **foo.o** from
23936 **foo.c** is used, with **$<** equal to **foo.c** and **$?** equal to **foo.h**. If **foo.c** is also newer than **foo.o**, **$<** is
23937 equal to **foo.c** and **$?** is equal to **foo.h foo.c**.

23938 **EXAMPLES**

23939 1. The following command:

23940 `make`

23941 makes the first target found in the makefile.

2. The following command:

```
make junk
```

makes the target **junk**.

3. The following makefile says that **pgm** depends on two files, **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**), and a common file **incl.h**:

```
pgm: a.o b.o
    c99 a.o b.o –o pgm
a.o: incl.h a.c
    c99 –c a.c
b.o: incl.h b.c
    c99 –c b.c
```

4. An example for making optimized **.o** files from **.c** files is:

```
.c.o:
    c99 –c –O $*.c
```

or:

```
.c.o:
    c99 –c –O $<
```

5. The most common use of the archive interface follows. Here, it is assumed that the source files are all C-language source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
    @echo lib is now up-to-date
```

The **.c.a** rule is used to make **file1.o**, **file2.o**, and **file3.o** and insert them into **lib**.

The treatment of escaped <newline> characters throughout the makefile is historical practice. For example, the inference rule:

```
.c.o\
:
```

works, and the macro:

```
f=  bar baz\
    biz
a:
    echo ==$f==
```

echoes "==bar baz biz==".

If **$?** were:

```
/usr/include/stdio.h /usr/include/unistd.h foo.h
```

then **$(?D)** would be:

```
/usr/include /usr/include .
```

and **$(?F)** would be:

```
stdio.h unistd.h foo.h
```

6. The contents of the built-in rules can be viewed by running:

```
make –p –f /dev/null 2>/dev/null
```

RATIONALE

The *make* utility described in this volume of IEEE Std. 1003.1-200x is intended to provide the means for changing portable source code into executables that can be run on a IEEE Std. 1003.1-200x-conforming system. It reflects the most common features present in System V and BSD *make*s.

Historically, the *make* utility has been an especially fertile ground for vendor and research organization-specific syntax modifications and extensions. Examples include:

- Syntax supporting parallel execution (such as from various multiprocessor vendors, GNU, and others)
- Additional ‘‘operators’’ separating targets and their prerequisites (System V, BSD, and others)
- Specifying that command lines containing the strings **${MAKE}** and **$(MAKE)** are executed when the **–n** option is specified (GNU and System V)
- Modifications of the meaning of internal macros when referencing libraries (BSD and others)
- Using a single instance of the shell for all of the command lines of the target (BSD and others)
- Allowing spaces as well as tabs to delimit command lines (BSD)
- Adding C preprocessor-style ‘‘include’’ and ‘‘ifdef’’ constructs (System V, GNU, BSD, and others)
- Remote execution of command lines (Sprite and others)
- Specifying additional special targets (BSD, System V, and most others)

Additionally, many vendors and research organizations have rethought the basic concepts of *make*, creating vastly extended, as well as completely new, syntaxes. Each of these versions of *make* fulfills the needs of a different community of users; it is unreasonable for this volume of IEEE Std. 1003.1-200x to require behavior that would be incompatible (and probably inferior) to historical practice for such a community.

In similar circumstances, when the industry has enough sufficiently incompatible formats as to make them irreconcilable, this volume of IEEE Std. 1003.1-200x has followed one or both of two courses of action. Commands have been renamed (*cksum*, *echo*, and *pax*) and/or command line options have been provided to select the desired behavior (*grep*, *od*, and *pax*).

Because the syntax specified for the *make* utility is, by and large, a subset of the syntaxes accepted by almost all versions of *make*, it was decided that it would be counter-productive to change the name. And since the makefile itself is a basic unit of portability, it would not be completely effective to reserve a new option letter, such as *make* **–P**, to achieve the portable behavior. Therefore, the special target **.POSIX** was added to the makefile, allowing users to specify ‘‘standard’’ behavior. This special target does not preclude extensions in the *make* utility, nor does it preclude such extensions being used by the makefile specifying the target; it does, however, preclude any extensions from being applied that could alter the behavior of previously valid syntax; such extensions must be controlled via command line options or new special targets. It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The portable version of *make* described in this reference page is not intended to be the state-of-the-art software generation tool and, as such, some newer and more leading-edge features have not been included. An attempt has been made to describe the portable makefile in a manner that does not preclude such extensions as long as they do not disturb the portable behavior described

here.

When the **–n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* **–n** *target* to be used to see all of the action that would be taken to update *target*.

The definition of *MAKEFLAGS* allows both the System V letter string and the BSD command line formats. The two formats are sufficiently different to allow implementations to support both without ambiguity.

Early proposals stated that an ''unquoted'' number sign was treated as the start of a comment. The *make* utility does not pay any attention to quotes. A number sign starts a comment regardless of its surroundings.

The text about ''other implementation-defined path names may also be tried'' in addition to **./makefile** and **./Makefile** is to allow such extensions as **SCCS/s.Makefile** and other variations. It was made an implementation-defined requirement (as opposed to unspecified behavior) to highlight surprising implementations that might select something unexpected like **/etc/Makefile**. XSI-conformant systems also try **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile**.

Early proposals contained the macro **NPROC** as a means of specifying that *make* should use *n* processes to do the work required. While this feature is a valuable extension for many systems, it is not common usage and could require other non-trivial extensions to makefile syntax. This extension is not required by this volume of IEEE Std. 1003.1-200x, but could be provided as a compatible extension. The macro **PARALLEL** is used by some historical systems with essentially the same meaning (but without using a name that is a common system limit value). It is suggested that implementors recognize the existing use of **NPROC** and/or **PARALLEL** as extensions to *make*.

The default rules are based on System V. The default **CC=** value is *c99* instead of *cc* because this volume of IEEE Std. 1003.1-200x does not standardize the utility named *cc*. Thus, every conforming application would be required to define **CC=***c99* to expect to run. There is no advantage conferred by the hope that the makefile might hit the ''preferred'' compiler because this cannot be guaranteed to work. Also, since the portable makescript can only use the *c99* options, no advantage is conferred in terms of what the script can do. It is a quality-of-implementation issue as to whether *c99* is as valuable as *cc*.

The **–d** option to *make* is frequently used to produce debugging information, but is too implementation-defined to add to this volume of IEEE Std. 1003.1-200x.

The **–p** option is not passed in *MAKEFLAGS* on most historical implementations and to change this would cause many implementations to break without sufficiently increased portability.

Commands that begin with a plus sign (`'+'`) are executed even if the **–n** option is present. Based on the GNU version of *make*, the behavior of **–n** when the plus-sign prefix is encountered has been extended to apply to **–q** and **–t** as well. However, the System V convention of forcing command execution with **–n** when the command line of a target contains either of the strings **$(MAKE)** or **${MAKE}** has not been adopted. This functionality appeared in early proposals, but the danger of this approach was pointed out with the following example of a portion of a makefile:

```
subdir:
    cd subdir; rm all_the_files; $(MAKE)
```

The loss of the System V behavior in this case is well-balanced by the safety afforded to other makefiles that were not aware of this situation. In any event, the command line plus-sign prefix can provide the desired functionality.

The double colon in the target rule format is supported in BSD systems to allow more than one target line containing the same target name to have commands associated with it. Since this is not functionality described in the SVID or XPG3 it has been allowed as an extension, but not mandated.

The default rules are provided with text specifying that the built-in rules shall be the same *as if* the listed set were used. The intent is that implementations should be able to use the rules without change, but will be allowed to alter them in ways that do not affect the primary behavior.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other portions of this volume of IEEE Std. 1003.1-200x. The default rules include rules for optional commands in this volume of IEEE Std. 1003.1-200x. Only rules pertaining to commands that are provided are needed in the default set of an implementation.

One point of discussion was whether to drop the default rules list from this volume of IEEE Std. 1003.1-200x. They provide convenience, but do not enhance portability of applications. The prime benefit is in portability of users who wish to type *make command* and have the command build from a **command.c** file.

The historical *MAKESHELL* feature was omitted. In some implementations it is used to let a user override the shell to be used to run *make* commands. This was confusing; for a portable *make*, the shell should be chosen by the makefile writer or specified on the *make* command line and not by a user running *make*.

The *make* utilities in most historical implementations process the prerequisites of a target in left-to-right order, and the makefile format requires this. It supports the standard idiom used in many makefiles that produce *yacc* programs; for example:

```
foo: y.tab.o lex.o main.o
    $(CC) $(CFLAGS) –o $@ t.tab.o lex.o main.o
```

In this example, if *make* chose any arbitrary order, the **lex.o** might not be made with the correct **y.tab.h**. Although there may be better ways to express this relationship, it is widely used historically. Implementations that desire to update prerequisites in parallel should require an explicit extension to *make* or the makefile format to accomplish it, as described previously.

The algorithm for determining a new entry for target rules is partially unspecified. Some historical *make*s allow blank, empty, or comment lines within the collection of commands marked by leading <tab>s. A conforming makefile must ensure that each command starts with a <tab>, but implementations are free to ignore blank, empty, and comment lines without triggering the start of a new entry.

The ASYNCHRONOUS EVENTS section includes having SIGTERM and SIGHUP, along with the more traditional SIGINT and SIGQUIT, remove the current target unless directed not to do so. SIGTERM and SIGHUP were added to parallel other utilities that have historically cleaned up their work as a result of these signals. When *make* receives any signal other than SIGQUIT, it is required to resend itself the signal it received so that it exits with a status that reflects the signal. The results from SIGQUIT are partially unspecified because, on systems that create **core** files upon receipt of SIGQUIT, the **core** from *make* would conflict with a core file from the command that was running when the SIGQUIT arrived. The main concern was to prevent damaged files from appearing up-to-date when *make* is rerun.

The **.PRECIOUS** special target was extended to affect all targets globally (by specifying no prerequisites). The **.IGNORE** and **.SILENT** special targets were extended to allow prerequisites; it was judged to be more useful in some cases to be able to turn off errors or echoing for a list of

24119 targets than for the entire makefile. These extensions to the *make* in System V were made to
24120 match historical practice from the BSD *make*.

24121 Macros are not exported to the environment of commands to be run. This was never the case in
24122 any historical *make* and would have serious consequences. The environment is the same as the
24123 environment to *make* except that *MAKEFLAGS* and macros defined on the *make* command line
24124 are added.

24125 Some implementations do not use *system*( ) for all command lines, as required by the portable
24126 makefile format; as a performance enhancement, they select lines without shell metacharacters
24127 for direct execution by *execve*( ). There is no requirement that *system*( ) be used specifically, but
24128 merely that the same results be achieved. The metacharacters typically used to bypass the direct
24129 *execve*( ) execution have been any of:

24130 `= | ^ ( ) ; & < > * ? [ ] : $ ‘ ’ " \ \n`

24131 The default in some advanced versions of *make* is to group all the command lines for a target and
24132 execute them using a single shell invocation; the System V method is to pass each line
24133 individually to a separate shell. The single-shell method has the advantages in performance and
24134 the lack of a requirement for many continued lines. However, converting to this newer method
24135 has caused portability problems with many historical makefiles, so the behavior with the POSIX
24136 makefile is specified to be the same as that of System V. It is suggested that the special target
24137 **.ONESHELL** be used as an implementation extension to achieve the single-shell grouping for a
24138 target or group of targets.

24139 Novice users of *make* have had difficulty with the historical need to start commands with a
24140 <tab> character. Since it is often difficult to discern differences between <tab> and <space>
24141 characters on terminals or printed listings, confusing bugs can arise. In early proposals, an
24142 attempt was made to correct this problem by allowing leading <blank>s instead of <tab>s.
24143 However, implementors reported many makefiles that failed in subtle ways following this
24144 change, and it is difficult to implement a *make* that unambiguously can differentiate between
24145 macro and command lines. There is extensive historical practice of allowing leading spaces
24146 before macro definitions. Forcing macro lines into column 1 would be a significant backwards-
24147 compatibility problem for some makefiles. Therefore, historical practice was restored.

24148 The System V INCLUDE feature was considered, but not included. This would treat a line that
24149 began in the first column and contained INCLUDE <*filename*> as an indication to read <*filename*>
24150 at that point in the makefile. This is difficult to use in a portable way, and it raises concerns
24151 about nesting levels and diagnostics. System V, BSD, GNU, and others have used different
24152 methods for including files.

24153 The System V dynamic dependency feature was not included. It would support:

24154 `cat: $$@.c`

24155 that would expand to;

24156 `cat: cat.c`

24157 This feature exists only in the new version of System V *make* and, while useful, is not in wide
24158 usage. This means that macros are expanded twice for prerequisites: once at makefile parse time
24159 and once at target update time.

24160 Consideration was given to adding metarules to the POSIX *make*. This would make **%.o: %.c** the
24161 same as **.c.o:**. This is quite useful and available from some vendors, but it would cause too many
24162 changes to this *make* to support. It would have introduced rule chaining and new substitution
24163 rules. However, the rules for target names have been set to reserve the `'%'` and `'"'` characters.
24164 These are traditionally used to implement metarules and quoting of target names, respectively.

Implementors are strongly encouraged to use these characters only for these purposes.

A request was made to extend the suffix delimiter character from a period to any character. The metarules feature in newer *make*s solves this problem in a more general way. This volume of IEEE Std. 1003.1-200x is staying with the more conservative historical definition.

The standard output format for the **–p** option is not described because it is primarily a debugging option and because the format is not generally useful to programs. In historical implementations the output is not suitable for use in generating makefiles. The **–p** format has been variable across historical implementations. Therefore, the definition of **–p** was only to provide a consistently named option for obtaining *make* script debugging information.

Some historical implementations have not cleared the suffix list with **–r**.

Implementations should be aware that some historical applications have intermixed *target_name* and *macro=value* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Portable applications do not do this, but some backwards-compatibility support may be warranted.

Empty inference rules are specified with a semicolon command rather than omitting all commands, as described in an early proposal. The latter case has no traditional meaning and is reserved for implementation extensions, such as in GNU *make*.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 4, Version 2

Under **Default Rules**, the string `"–G$@"` is deleted from the line referencing *sccs*.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the Software Development Utilities option.

The Open Group corrigenda item U029/1 has been applied, correcting a typographical error in the SPECIAL TARGETS section.

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ‘‘otherwise, the home directory of a user of that name is examined’’ to ‘‘otherwise, the value of *PROJECTDIR* is treated as a user name and that user’s initial working directory is examined’’.

It is specified whether the command line is related to the makefile or to the *make* command, and the macro processing rules are updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

man — display system documentation

SYNOPSIS

```
man [–k] name...
```

DESCRIPTION

The *man* utility shall write information about each of the *name* operands. If *name* is the name of a standard utility, *man* at a minimum shall write a message describing the syntax used by the standard utility, its options, and operands. If more information is available, the *man* utility shall provide it in an implementation-defined manner.

An implementation may provide information for values of *name* other than the standard utilities. Standard utilities that are listed as optional and that are not supported by the implementation either shall cause a brief message indicating that fact to be displayed or shall cause a full display of information as described previously.

OPTIONS

The *man* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–k Interpret *name* operands as keywords to be used in searching a utilities summary database that contains a brief purpose entry for each standard utility and write lines from the summary database that match any of the keywords. The keyword search shall produce results that are the equivalent of the output of the following command:

```
grep –Ei '
name
name
...
' summary-database
```

This assumes that the *summary-database* is a text file with a single entry per line; this organization is not required and the example using *grep* –**Ei** is merely illustrative of the type of search intended. The purpose entry to be included in the database shall consist of a terse description of the purpose of the utility.

OPERANDS

The following operand shall be supported:

name A keyword or the name of a standard utility. When –**k** is not specified and *name* does not represent one of the standard utilities, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *man*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and in the summary database). The value of *LC_CTYPE* need not affect the format of the information written about the name operands.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PAGER Determine an output filtering command for writing the output to a terminal. Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. When standard output is a terminal device, the reference page output shall be piped through the command. If the *PAGER* variable is null or not set, the command shall be either *more* or another paginator utility documented in the system documentation.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *man* utility shall write text describing the syntax of the utility *name*, its options and its operands, or, when **–k** is specified, lines from the summary database. The format of this text is implementation-defined.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

It is recognized that the *man* utility is only of minimal usefulness as specified. The opinion of the standard developers was strongly divided as to how much or how little information *man* should be required to provide. They considered, however, that the provision of some portable way of accessing documentation would aid user portability. The arguments against a fuller

specification were:

- Large quantities of documentation should not be required on a system that does not have excess disk space.
- The current manual system does not present information in a manner that greatly aids user portability.
- A ‘‘better help system’’ is currently an area in which vendors feel that they can add value to their POSIX implementations.

The **–f** option was considered, but due to implementation differences, it was not included in this volume of IEEE Std. 1003.1-200x.

The description was changed to be more specific about what has to be displayed for a utility. The standard developers considered it insufficient to allow a display of only the synopsis without giving a short description of what each option and operand does.

The ‘‘purpose’’ entry to be included in the database can be similar to the section title (less the numeric prefix) from this volume of IEEE Std. 1003.1-200x for each utility. These titles are similar to those used in historical systems for this purpose.

See *mailx* for rationale concerning the default paginator.

The caveat in the *LC_CTYPE* description was added because it is not a requirement that an implementation provide reference pages for all of its supported locales on each system; changing *LC_CTYPE* does not necessarily translate the reference page into another language. This is equivalent to the current state of *LC_MESSAGES* in IEEE Std. 1003.1-200x—locale-specific messages are not yet a requirement.

The historical *MANPATH* variable is not included in POSIX because no attempt is made to specify naming conventions for reference page files, nor even to mandate that they are files at all. In some systems they could be a true database, a hypertext file, or even fixed strings within the *man* executable. The standard developers considered the portability of reference pages to be outside their scope of work (and more appropriate to the POSIX.7 working group developing application-installation tools). However, users should be aware that *MANPATH* is implemented on a number of historical systems and that it can be used to tailor the search pattern for reference pages from the various categories (utilities, functions, file formats, and so on) when the system administrator reveals the location and conventions for reference pages on the system.

The keyword search can rely on at least the text of the section titles from these utility descriptions, and the implementation may add more keywords. The term ‘‘section titles’’ refers to the strings such as:

```
man — Display system documentation
ps — Report process status
```

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

NAME

mesg — permit or deny messages

SYNOPSIS

UP

```
mesg [y|n]
```

DESCRIPTION

The *mesg* utility shall control whether other users are allowed to send messages via *write*, *talk*, or other utilities to a terminal device. The terminal device affected shall be determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, *mesg* shall report the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

OPTIONS

None.

OPERANDS

The following operands shall be supported in the POSIX locale:

y Grant permission to other users to send messages to the terminal device.

n Deny permission to other users to send messages to the terminal device.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mesg*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written (by *mesg*) to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no operand is specified, *mesg* shall display the current terminal state in an unspecified format.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Receiving messages is allowed.

1 Receiving messages is not allowed.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The mechanism by which the message status of the terminal is changed is unspecified. Therefore, unspecified actions may cause the status of the terminal to change after *mesg* has successfully completed. These actions may include, but are not limited to: another invocation of the *mesg* utility, login procedures; invocation of the *stty* utility, invocation of the *chmod* utility or *chmod*( ) function, and so on.

EXAMPLES

None.

RATIONALE

The terminal changed by *mesg* is that associated with the standard input, output, or error, rather than the controlling terminal for the session. This is because users logged in more than once should be able to change any of their login terminals without having to stop the job running in those sessions. This is not a security problem involving the terminals of other users because appropriate privileges would be required to affect the terminal of another user.

The method of checking each of the first three file descriptors in sequence until a terminal is found was adopted from System V.

The file **/dev/tty** is not specified for the terminal device because it was thought to be too restrictive. Typical environment changes for the **n** operand are that write permissions are removed for *others* and *group* from the appropriate device. It was decided to leave the actual description of what is done as unspecified because of potential differences between implementations.

The format for standard output is unspecified because of differences between historical implementations. This output is generally not useful to shell scripts (they can use the exit status), so exact parsing of the output is unnecessary.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

NAME

mkdir — make directories

SYNOPSIS

```
mkdir [–p][–m mode] dir...
```

DESCRIPTION

The *mkdir* utility shall create the directories specified by the operands, in the order specified.

For each *dir* operand, the *mkdir* utility shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, called with the following arguments:

1. The *dir* operand is used as the *path* argument.
2. The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO is used as the *mode* argument. (If the **–m** option is specified, the *mode* option-argument overrides this default.)

OPTIONS

The *mkdir* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–m *mode* Set the file permission bits of the newly-created directory to the specified *mode* value. The *mode* option-argument shall be the same as the *mode* operand defined for the *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'–'` shall be interpreted relative to an assumed initial mode of *a=rwx*; `'+'` shall add permissions to the default mode, `'–'` shall delete permissions from the default mode.

–p Create any missing intermediate path name components.

For each *dir* operand that does not name an existing directory, effects equivalent to those caused by the following command shall occur:

```
mkdir –p –m $(umask –S),u+wx $(dirname dir) &&
mkdir [–m mode] dir
```

where the **–m** *mode* option represents that option supplied to the original invocation of *mkdir*, if any.

Each *dir* operand that names an existing directory shall be ignored without error.

OPERANDS

The following operand shall be supported:

dir A path name of a directory to be created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mkdir*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables

contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 All the specified directories were created successfully or the **−p** option was specified and all the specified directories now exist.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The default file mode for directories is *a=rwx* (777 on most systems) with selected permissions removed in accordance with the file mode creation mask. For intermediate path name components created by *mkdir*, the mode is the default modified by *u+wx* so that the subdirectories can always be created regardless of the file mode creation mask; if different ultimate permissions are desired for the intermediate directories, they can be changed afterwards with *chmod*.

Note that some of the requested directories may have been created even if an error occurs.

EXAMPLES
None.

RATIONALE
The System V **−m** option was included to control the file mode.

The System V **−p** option was included to create any needed intermediate directories and to complement the functionality provided by *rmdir* for removing directories in the path prefix as they become empty. Because no error is produced if any path component already exists, the **−p**

option is also useful to ensure that a particular directory exists.

The functionality of *mkdir* is described substantially through a reference to the *mkdir*( ) function in the System Interfaces volume of IEEE Std. 1003.1-200x. For example, by default, the mode of the directory is affected by the file mode creation mask in accordance with the specified behavior of the *mkdir*( ) function. In this way, there is less duplication of effort required for describing details of the directory creation.

FUTURE DIRECTIONS

None.

24527 **NAME**

24528 mkfifo — make FIFO special files

24529 **SYNOPSIS**

24530 `mkfifo [–m mode] file...`

24531 **DESCRIPTION**

24532 The *mkfifo* utility shall create the FIFO special files specified by the operands, in the order
24533 specified.

24534 For each *file* operand, the *mkfifo* utility shall perform actions equivalent to the *mkfifo*() function
24535 defined in the System Interfaces volume of IEEE Std. 1003.1-200x, called with the following
24536 arguments:

24537 1. The *file* operand is used as the *path* argument.

24538 2. The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP,
24539 S_IROTH, and S_IWOTH is used as the *mode* argument. (If the **–m** option is specified, the
24540 value of the *mkfifo*() *mode* argument is unspecified, but the FIFO shall at no time have
24541 permissions less restrictive than the **–m** *mode* option-argument.)

24542 **OPTIONS**

24543 The *mkfifo* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
24544 12.2, Utility Syntax Guidelines.

24545 The following option shall be supported:

24546 **–m** *mode* Set the file permission bits of the newly-created FIFO to the specified *mode* value.
24547 The *mode* option-argument shall be the same as the *mode* operand defined for the
24548 *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'–'` shall be
24549 interpreted relative to an assumed initial mode of *a=rw*.

24550 **OPERANDS**

24551 The following operand shall be supported:

24552 *file* A path name of the FIFO special file to be created.

24553 **STDIN**

24554 Not used.

24555 **INPUT FILES**

24556 None.

24557 **ENVIRONMENT VARIABLES**

24558 The following environment variables shall affect the execution of *mkfifo*:

24559 *LANG* Provide a default value for the internationalization variables that are unset or null.
24560 If *LANG* is unset or null, the corresponding value from the implementation-
24561 defined default locale shall be used. If any of the internationalization variables
24562 contains an invalid setting, the utility shall behave as if none of the variables had
24563 been defined.

24564 *LC_ALL* If set to a non-empty string value, override the values of all the other
24565 internationalization variables.

24566 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
24567 characters (for example, single-byte as opposed to multi-byte characters in
24568 arguments).

24569 *LC_MESSAGES*

24570 Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All the specified FIFO special files were created successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

This new utility was added to permit shell applications to create FIFO special files.

The **−m** option was added to control the file mode, for consistency with the similar functionality provided the *mkdir* utility.

Early proposals included a **−p** option similar to the *mkdir* **−p** option that created intermediate directories leading up to the FIFO specified by the final component. This was removed because it is not commonly needed and is not common practice with similar utilities.

The functionality of *mkfifo* is described substantially through a reference to the *mkfifo*( ) function in the System Interfaces volume of IEEE Std. 1003.1-200x. For example, by default, the mode of the FIFO file is affected by the file mode creation mask in accordance with the specified behavior of the *mkfifo*( ) function. In this way, there is less duplication of effort required for describing details of the file creation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

24611 **Issue 4**
24612 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

more — display files on a page-by-page basis

SYNOPSIS

UP

```
more [–ceisu][–n number][–p command][–t tagstring][file ...]
```

DESCRIPTION

The *more* utility shall read files and either write them to the terminal on a page-by-page basis or filter them to standard output. If standard output is not a terminal device, all input files shall be copied to standard output in their entirety, without modification, except as specified for the **–s** option. If standard output is a terminal device, the files shall be written a number of lines (one screenful) at a time under the control of user commands. See the EXTENDED DESCRIPTION section.

Certain block-mode terminals do not have all the capabilities necessary to support the complete *more* definition; they are incapable of accepting commands that are not terminated with a <newline> character. Implementations that support such terminals shall provide an operating mode to *more* in which all commands can be terminated with a <newline> character on those terminals. This mode:

- Shall be documented in the system documentation
- Shall, at invocation, inform the user of the terminal deficiency that requires the <newline> character usage and provide instructions on how this warning can be suppressed in future invocations
- Shall not be required for implementations supporting only fully capable terminals
- Shall not affect commands already requiring <newline> characters
- Shall not affect users on the capable terminals from using *more* as described in this volume of IEEE Std. 1003.1-200x

OPTIONS

The *more* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–c If a screen is to be written that has no lines in common with the current screen, or *more* is writing its first screen, *more* does not scroll the screen, but instead redraws each line of the screen in turn, from the top of the screen to the bottom. In addition, if *more* is writing its first screen, the screen is cleared. This option may be silently ignored on devices with insufficient terminal capabilities.

–e By default, *more* shall exit immediately after writing the last line of the last file in the argument list. If the **–e** option is specified:

1. If there is only a single file in the argument list and that file was completely displayed on a single screen, *more* shall exit immediately after writing the last line of that file.
2. Otherwise, *more* shall exit only after reaching end-of-file on the last file in the argument list twice without an intervening operation. See the EXTENDED DESCRIPTION section.

–i Perform pattern matching in searches without regard to case; see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.2, Regular Expression General Requirements .

24658 –**n** *number* Specify the number of lines per screenful. The *number* argument is a positive
24659 decimal integer. The –**n** option shall override any values obtained from any other
24660 source.

24661 –**p** *command* Each time a screen from a new file is displayed or redisplayed (including as a
24662 result of *more* commands; for example, **:p**), execute the *more* command(s) in the
24663 command arguments in the order specified, as if entered by the user after the first
24664 screen has been displayed. No intermediate results shall be displayed (that is, if the
24665 command is a movement to a screen different than the normal first screen, only the
24666 screen resulting from the command shall be displayed.) If any of the commands
24667 fail for any reason, an informational message to this effect shall be written, and no
24668 further commands specified using the –**p** option shall be executed for this file.

24669 –**s** Behave as if consecutive empty lines were a single empty line.

24670 –**t** *tagstring* Write the screenful of the file containing the tag named by the *tagstring* argument.
24671 See the *ctags* utility. The tags feature represented by –**t** *tagstring* and the **:t**
24672 command is optional. It shall be provided on any system that also provides a
24673 conforming implementation of *ctags*; otherwise, the use of –**t** produces undefined
24674 results.

24675 The file name resulting from the –**t** option shall be logically added as a prefix to the
24676 list of command line files, as if specified by the user. If the tag named by the
24677 *tagstring* argument is not found, it shall be an error, and *more* shall take no further
24678 action.

24679 If the tag specifies a line number, the first line of the display shall contain the
24680 beginning of that line. If the tag specifies a pattern, the first line of the display shall
24681 contain the beginning of the matching text from the first line of the file that
24682 contains that pattern. If the line does not exist in the file or matching text is not
24683 found, an informational message to this effect shall be displayed, and *more* shall
24684 display the default screen as if –**t** had not been specified.

24685 If both the –**t** *tagstring* and –**p** *command* options are given, the –**t** *tagstring* shall be
24686 processed first; that is, the file and starting line for the display shall be as specified
24687 by –**t**, and then the –**p** *more* command shall be executed. If the line (matching text)
24688 specified by the –**t** command does not exist (is not found), no –**p** *more* command
24689 shall be executed for this file at any time.

24690 –**u** Treat a <backspace> character as a printable control character, displayed as an |
24691 implementation-defined character sequence (see the EXTENDED DESCRIPTION |
24692 section), suppressing backspacing and the special handling that produces
24693 underlined or standout mode text on some terminal types. Also, do not ignore a
24694 <carriage-return> character at the end of a line.

24695 **OPERANDS**

24696 The following operand shall be supported:

24697 *file* A path name of an input file. If no *file* operands are specified, the standard input
24698 shall be used. If a *file* is `'–'`, the standard input shall be read at that point in the
24699 sequence.

24700 **STDIN**

24701 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

INPUT FILES

The input files being examined shall be text files. If standard output is a terminal, standard error shall be used to read commands from the user. If standard output is a terminal, standard error is not readable, and command input is needed, *more* may attempt to obtain user commands from the controlling terminal (for example, **/dev/tty**); otherwise, *more* shall terminate with an error indicating that it was unable to read user commands. If standard output is not a terminal, no error shall result if standard error cannot be opened for reading.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *more*:

COLUMNS Override the system-selected horizontal screen size. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

EDITOR Used by the **v** command to select an editor. See the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null. The **–n** option shall take precedence over the *LINES* variable for determining the number of lines in a screenful.

MORE Determine a string containing options described in the OPTIONS section preceded with hyphens and <blank> character-separated as on the command line. Any command line options shall be processed after those in the *MORE* variable, as if the command line were:

```
more $MORE options operands
```

The *MORE* variable shall take precedence over the *TERM* and *LINES* variables for determining the number of lines in a screenful.

24747 *TERM* Determine the name of the terminal type. If this variable is unset or null, an
24748 unspecified default terminal type is used.

24749 **ASYNCHRONOUS EVENTS**
24750 Default.

24751 **STDOUT**
24752 The standard output shall be used to write the contents of the input files.

24753 **STDERR**
24754 Used for diagnostic messages and user commands (see the INPUT FILES section), and, if
24755 standard output is a terminal device, to write a prompting string. The prompting string shall
24756 appear on the screen line below the last line of the file displayed in the current screenful. The
24757 prompt shall contain the name of the file currently being examined and shall contain an end-of-
24758 file indication and the name of the next file, if any, when prompting at the end-of-file. If an error
24759 or informational message is displayed, it is unspecified whether it is contained in the prompt. If
24760 it is not contained in the prompt, it shall be displayed and then the user shall be prompted for a
24761 continuation character, at which point another message or the user prompt may be displayed.
24762 The prompt is otherwise unspecified. It is unspecified whether informational messages are
24763 written for other user commands.

24764 **OUTPUT FILES**
24765 None.

24766 **EXTENDED DESCRIPTION**
24767 The following subsection describes the behavior of *more* when the standard output is a terminal
24768 device. If the standard output is not a terminal device, no options other than **–s** shall have any
24769 effect, and all input files shall be copied to standard output otherwise unmodified, at which time
24770 *more* shall exit without further action.

24771 The number of lines available per screen shall be determined by the **–n** option, if present, or by
24772 examining values in the environment (see the ENVIRONMENT VARIABLES section). If neither
24773 method yields a number, an unspecified number of lines shall be used.

24774 The maximum number of lines written shall be one less than this number, because the screen
24775 line after the last line written shall be used to write a user prompt and user input. If the number
24776 of lines in the screen is less than two, the results are undefined. It is unspecified whether user
24777 input is permitted to be longer than the remainder of the single line where the prompt has been
24778 written.

24779 The number of columns available per line shall be determined by examining values in the
24780 environment (see the ENVIRONMENT VARIABLES section), with a default value as described
24781 in Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

24782 Lines that are longer than the display shall be folded; the length at which folding occurs is
24783 unspecified, but should be appropriate for the output device. Folding may occur between glyphs
24784 of single characters that take up multiple display columns.

24785 When standard output is a terminal and **–u** is not specified, *more* shall treat <backspace>
24786 characters and <carriage-return> characters specially:

24787 • A character, followed first by a sequence of *n* <backspace> characters (where *n* is the same as
24788 the number of column positions that the character occupies), then by *n* underscore characters
24789 ('_'), shall cause that character to be written as underlined text, if the terminal type
24790 supports that. The *n* underscore characters, followed first by *n* <backspace> characters, then
24791 any character with *n* column positions, shall also cause that character to be written as
24792 underlined text, if the terminal type supports that.

- A sequence of *n* <backspace> characters (where *n* is the same as the number of column positions that the previous character occupies) that appears between two identical printable characters shall cause the first of those two characters to be written as emboldened text (that is, visually brighter, standout mode, or inverse-video mode), if the terminal type supports that, and the second to be discarded. Immediately subsequent occurrences of <backspace>/character pairs for that same character also shall be discarded. (For example, the sequence `"a\ba\ba\ba"` is interpreted as a single emboldened `'a'`.)
- The *more* utility shall logically discard all other <backspace> characters from the line as well as the character which precedes them, if any.
- A <carriage-return> character at the end of a line shall be ignored, rather than being written as a non-printable character, as described in the next paragraph.

It is implementation-defined how other non-printable characters are written. Implementations should use the same format that they use for the *ex* **print** command; see the OPTIONS section within the *ed* utility. It is unspecified whether a multi-column character shall be separated if it crosses a logical line boundary; it shall not be discarded. The behavior is unspecified if the number of columns on the display is less than the number of columns any single character in the line being displayed would occupy.

When each new file is displayed (or redisplayed), *more* shall write the first screen of the file. Once the initial screen has been written, *more* shall prompt for a user command. If the execution of the user command results in a screen that has lines in common with the current screen, and the device has sufficient terminal capabilities, *more* shall scroll the screen; otherwise, it is unspecified whether the screen is scrolled or redrawn.

For all files but the last (including standard input if no file was specified, and for the last file as well, if the **–e** option was not specified), when *more* has written the last line in the file, *more* shall prompt for a user command. This prompt shall contain the name of the next file as well as an indication that *more* has reached end-of-file. If the user command is **f**, <control>-F, <space>, **j**, <newline>, **d**, <control>-D, or **s**, *more* shall display the next file. Otherwise, if displaying the last file, *more* shall exit. Otherwise, *more* shall execute the user command specified.

Several of the commands described in this section display a previous screen from the input stream. In the case that text is being taken from a non-rewindable stream, such as a pipe, it is implementation-defined how much backwards motion is supported. If a command cannot be executed because of a limitation on backwards motion, an error message to this effect shall be displayed, the current screen shall not change, and the user shall be prompted for another command.

If a command cannot be performed because there are insufficient lines to display, *more* shall alert the terminal. If a command cannot be performed because there are insufficient lines to display or a **/** command fails: if the input is the standard input, the last screen in the file may be displayed; otherwise, the current file and screen shall not change, and the user shall be prompted for another command.

The interactive commands in the following sections shall be supported. Some commands can be preceded by a decimal integer, called *count* in the following descriptions. If not specified with the command, *count* shall default to 1. In the following descriptions, *pattern* is a basic regular expression, as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions. The term ‘‘examine’’ is historical usage meaning ‘‘open the file for viewing’’; for example, *more* **foo** would be expressed as examining file **foo**. In the following descriptions, unless otherwise specified, *line* is a logical line in the *more* display, not a line from the file being examined.

In the following descriptions, the *current position* refers to two things:

1. The position of the current line on the screen
2. The line number (in the file) of the current line on the screen

Usually, the line on the screen corresponding to the current position is the third line on the screen. If this is not possible (there are fewer than three lines to display or this is the first page of the file, or it is the last page of the file), then the current position is either the first or last line on the screen as described later.

Help

Synopsis: `h`

Write a summary of these commands and other implementation-defined commands. The behavior shall be as if the *more* utility were executed with the **–e** option on a file that contained the summary information. The user shall be prompted as described earlier in this section when end-of-file is reached. If the user command is one of those specified to continue to the next file, *more* shall return to the file and screen state from which the **h** command was executed.

Scroll Forward One Screenful

Synopsis: `[`*count*`]f`
`[`*count*`]<control>-F`

Scroll forward *count* lines, with a default of one screenful. If *count* is more than the screen size, only the final screenful shall be written.

Scroll Backward One Screenful

Synopsis: `[`*count*`]b`
`[`*count*`]<control>-B`

Scroll backward *count* lines, with a default of one screenful (see the **–n** option). If *count* is more than the screen size, only the final screenful shall be written.

Scroll Forward One Line

Synopsis: `[`*count*`]<space>`
`[`*count*`]j`
`[`*count*`]<newline>`

Scroll forward *count* lines. The default *count* for the <space> character shall be one screenful; for **j** and <newline> character, one line. The entire *count* lines shall be written, even if *count* is more than the screen size.

Scroll Backward One Line

Synopsis: `[`*count*`]k`

Scroll backward *count* lines. The entire *count* lines shall be written, even if *count* is more than the screen size.

24875 **Scroll Forward One Half Screenful**

24876 *Synopsis*: `[`*count*`]d`
24877 `[`*count*`]<control>-D`

24878 Scroll forward *count* lines, with a default of one half of the screen size. If *count* is specified, it
24879 shall become the new default for subsequent **d**, <control>-D, and **u** commands.

24880 **Skip Forward One Line**

24881 *Synopsis*: `[`*count*`]s`

24882 Display the screenful beginning with the line *count* lines after the last line on the current screen.
24883 If *count* would cause the current position to be such that less than one screenful would be
24884 written, the last screenful in the file shall be written.

24885 **Scroll Backward One Half Screenful**

24886 *Synopsis*: `[`*count*`]u`
24887 `[`*count*`]<control>-U`

24888 Scroll backward *count* lines, with a default of one half of the screen size. If *count* is specified, it
24889 shall become the new default for subsequent **d**, <control>–D, **u**, and <control>–U commands.
24890 The entire *count* lines shall be written, even if *count* is more than the screen size.

24891 **Go to Beginning of File**

24892 *Synopsis*: `[`*count*`]g`

24893 Display the screenful beginning with line *count*.

24894 **Go to End-of-File**

24895 *Synopsis*: `[`*count*`]G`

24896 If *count* is specified, display the screenful beginning with the line *count*. Otherwise, display the
24897 last screenful of the file.

24898 **Refresh the Screen**

24899 *Synopsis*: `r`
24900 `<control>-L`

24901 Refresh the screen.

24902 **Discard and Refresh**

24903 *Synopsis*: `R`

24904 Refresh the screen, discarding any buffered input. If the current file is non-seekable, buffered
24905 input shall not be discarded and the **R** command is equivalent to the **r** command.

24906 **Mark Position**

24907 *Synopsis*: `m`*`letter`*

24908 Mark the current position with the letter named by *letter*, where *letter* represents the name of one
24909 of the lowercase letters of the portable character set. When a new file is examined, all marks may
24910 be lost.

24911 **Return to Mark**

24912 *Synopsis*: `'`*`letter`*

24913 Return to the position that was previously marked with the letter named by *letter*, making that
24914 line the current position.

24915 **Return to Previous Position**

24916 *Synopsis*: `''`

24917 Return to the position from which the last large movement command was executed (where a
24918 ‘‘large movement’’ is defined as any movement of more than a screenful of lines). If no such
24919 movements have been made, return to the beginning of the file.

24920 **Search Forward for Pattern**

24921 *Synopsis*: **[***count***]/[**!**]***pattern***<**newline**>**

24922 Display the screenful beginning with the *count*th line containing the pattern. The search shall
24923 start after the first line currently displayed. The null regular expression (`'/'` followed by a
24924 <newline> character) shall repeat the search using the previous regular expression, with a
24925 default *count*. If the character `'!'` is included, the matching lines shall be those that do not
24926 contain the *pattern*. If no match is found for the *pattern*, a message to that effect shall be
24927 displayed.

24928 **Search Backward for Pattern**

24929 *Synopsis*: **[***count***]?[**!**]***pattern***<**newline**>**

24930 Display the screenful beginning with the *count*th previous line containing the pattern. The
24931 search shall start on the last line before the first line currently displayed. The null regular
24932 expression (`'?'` followed by a <newline> character) shall repeat the search using the previous
24933 regular expression, with a default *count*. If the character `'!'` is included, matching lines shall be
24934 those that do not contain the *pattern*.

24935 If no match is found for the *pattern*, a message to that effect shall be displayed.

24936 **Repeat Search**

24937 *Synopsis*: **[***count***]**n

24938 Repeat the previous search for *count*th line containing the last *pattern* (or not containing the last
24939 *pattern*, if the previous search was `"/!"` or `"?!"`).

24940 **Repeat Search in Reverse**

24941 *Synopsis*: **[***count***]**N

24942 Repeat the search in the opposite direction of the previous search for the *count*th line containing
24943 the last *pattern* (or not containing the last *pattern*, if the previous search was "/!" or "?!").

24944 **Examine New File**

24945 *Synopsis*: :e **[***filename***]**<newline>

24946 Examine a new file. If the *filename* argument is not specified, the current file (see the **:n** and **:p**
24947 commands below) shall be re-examined. The *filename* shall be subjected to the process of shell
24948 word expansions (see Section 2.6 (on page 2244)); if more than a single path name results, the
24949 effects are unspecified. If *filename* is a number sign ('#'), the previously examined file shall be
24950 re-examined. If *filename* is not accessible for any reason (including that it is a non-seekable file),
24951 an error message to this effect shall be displayed and the current file and screen shall not change.

24952 **Examine Next File**

24953 *Synopsis*: **[***count***]**:n

24954 Examine the next file. If a number *count* is specified, the *count*th next file shall be examined. If
24955 *filename* refers to a non-seekable file, the results are unspecified.

24956 **Examine Previous File**

24957 *Synopsis*: **[***count***]**:p

24958 Examine the previous file. If a number *count* is specified, the *count*th previous file shall be
24959 examined. If *filename* refers to a non-seekable file, the results are unspecified.

24960 **Go to Tag**

24961 *Synopsis*: :t *tagstring*<newline>

24962 If the file containing the tag named by the *tagstring* argument is not the current file, examine the
24963 file, as if the **:e** command was executed with that file as the argument. Otherwise, or in addition,
24964 display the screenful beginning with the tag, as described for the **–t** option (see the OPTIONS
24965 section). If the *ctags* utility is not supported by the system, the use of **:t** produces undefined
24966 results.

24967 **Invoke Editor**

24968 *Synopsis*: v

24969 Invoke an editor to edit the current file being examined. If standard input is being examined, the
24970 results are unspecified. The name of the editor shall be taken from the environment variable
24971 *EDITOR*, or shall default to *vi*. If the last path name component in *EDITOR* is either *vi* or *ex*, the
24972 editor shall be invoked with a **–c** *linenumber* command line argument, where *linenumber* is the |
24973 line number of the physical line containing the logical line currently displayed as the first line of
24974 the screen. It is implementation-defined whether line-setting options are passed to editors other |
24975 than *vi* and *ex*.

24976 When the editor exits, *more* shall resume with the same file and screen as when the editor was
24977 invoked.

24978 **Display Position**

24979 *Synopsis*: `=`
24980 `<control>-G`

24981 Write a message for which the information references the first byte of the line after the last line of
24982 the file on the screen. This message shall include the name of the file currently being examined,
24983 its number relative to the total number of files there are to examine, the physical line number,
24984 the byte number and the total bytes in the file, and what percentage of the file precedes the
24985 current position. If *more* is reading from standard input, or the file is shorter than a single screen,
24986 the line number, the byte number, the total bytes, and the percentage need not be written.

24987 **Quit**

24988 *Synopsis*: `q`
24989 `:q`
24990 `ZZ`

24991 Exit *more*.

24992 **EXIT STATUS**

24993 The following exit values shall be returned:

24994 0 Successful completion.

24995 >0 An error occurred.

24996 **CONSEQUENCES OF ERRORS**

24997 If an error is encountered accessing a file when using the **:n** command, *more* shall attempt to
24998 examine the next file in the argument list, but the final exit status shall be affected. If an error is
24999 encountered accessing a file via the **:p** command, *more* shall attempt to examine the previous file
25000 in the argument list, but the final exit status shall be affected. If an error is encountered accessing
25001 a file via the **:e** command, *more* shall remain in the current file and the final exit status shall not
25002 be affected.

25003 **APPLICATION USAGE**

25004 When the standard output is not a terminal, only the –**s** filter-modification option is effective.
25005 This is based on historical practice. For example, a typical implementation of *man* pipes its
25006 output through *more* –**s** to squeeze excess white space for terminal users. When *man* is piped to
25007 *lp*, however, it is undesirable for this squeezing to happen.

25008 **EXAMPLES**

25009 The –**p** allows arbitrary commands to be executed at the start of each file. Examples are:

25010 *more* –**p G** *file1 file2*
25011 Examine each file starting with its last screenful.

25012 *more* –**p** 100 *file1 file2*
25013 Examine each file starting with line 100 in the current position (usually the third line, so line
25014 98 would be the first line written).

25015 *more* –**p** /100 *file1 file2*
25016 Examine each file starting with the first line containing the string `"100"` in the current
25017 position

25018 **RATIONALE**

25019 The *more* utility, available in BSD and BSD-derived systems, was chosen as the prototype for the
25020 POSIX file display program since it is more widely available than either the public-domain
25021 program *less* or than *pg*, a pager provided in System V. The 4.4 BSD *more* is the model for the

25022 features selected; it is almost fully upward-compatible from the 4.3 BSD version in wide use and
25023 has become more amenable for *vi* users. Several features originally derived from various file
25024 editors, found in both *less* and *pg*, have been added to this volume of IEEE Std. 1003.1-200x as
25025 they have proved extremely popular with users.

25026 There are inconsistencies between *more* and *vi* that result from historical practice. For example,
25027 the single-character commands **h**, **f**, **b**, and <space> are screen movers in *more*, but cursor
25028 movers in *vi*. These inconsistencies were maintained because the cursor movements are not
25029 applicable to *more* and the powerful functionality achieved without the use of the control key
25030 justifies the differences.

25031 The tags interface has been included in a program that is not a text editor because it promotes
25032 another degree of consistent operation with *vi*. It is conceivable that the paging environment of
25033 *more* would be superior for browsing source code files in some circumstances.

25034 The operating mode referred to for block-mode terminals effectively adds a <newline> to each
25035 Synopsis line that currently has none. So, for example, **d**<newline> would page one screenful.
25036 The mode could be triggered by a command line option, environment variable, or some other
25037 method. The details are not imposed by this volume of IEEE Std. 1003.1-200x because there are
25038 so few systems known to support such terminals. Nevertheless, it was considered that all
25039 systems should be able to support *more* given the exception cited for this small community of
25040 terminals because, in comparison to *vi*, the cursor movements are few and the command set
25041 relatively amenable to the optional <newline>s.

25042 Some versions of *more* provide a shell escaping mechanism similar to the *ex* **!** command. The
25043 standard developers did not consider that this was necessary in a paginator, particularly given
25044 the wide acceptance of multiple window terminals and job control features. (They chose to
25045 retain such features in the editors and *mailx* because the shell interaction also gives an
25046 opportunity to modify the editing buffer, which is not applicable to *more*).

25047 The **–p** (position) option replaces the **+** command because of the Utility Syntax Guidelines. In
25048 early proposals, it took a *pattern* argument, but historical *less* provided the *more* general facility of
25049 a command. It would have been desirable to use the same **–c** as *ex* and *vi*, but the letter was
25050 already in use.

25051 The text stating ‘‘from a non-rewindable stream ... implementations may limit the amount of
25052 backwards motion supported’’ would allow an implementation that permitted no backwards
25053 motion beyond text already on the screen. It was not possible to require a minimum amount of
25054 backwards motion that would be effective for all conceivable device types. The implementation
25055 should allow the user to back up as far as possible, within device and reasonable memory
25056 allocation constraints.

25057 Historically, non-printable characters were displayed using the ARPA standard mappings,
25058 which are as follows:

25059 1. Printable characters are left alone.

25060 2. Control characters less than \177 are represented as followed by the character offset from
25061 the `'@'` character in the ASCII map; for example, \007 is represented as `'G'`.

25062 3. \177 is represented as followed by `'?'`.

25063 The display of characters having their eighth bit set was less standard. Existing implementations
25064 use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed characters with their
25065 eighth bit set as the two characters `"M–,"` followed by the seven bit display as described
25066 previously.) The latter probably has the best claim to historical practice because it was used with
25067 the **–v** option of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

No specific display format is required by IEEE Std. 1003.1-200x. Implementations are encouraged to conform to historic practice in the absence of any strong reason to diverge.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The utility has been extensively reworked for alignment with the IEEE P1003.2b draft standard:

- Changes have been made as result of IEEE PASC Interpretations 1003.2 #37 and #109.
- The *more* utility should be able to handle underlined and emboldened displays of characters that are wider than a single column position.

25085 **NAME**

25086 mv — move files

25087 **SYNOPSIS**

25088 `mv [–fi] source_file target_file`

25089 `mv [–fi] source_file... target_file`

25090 **DESCRIPTION**

25091 In the first synopsis form, the *mv* utility shall move the file named by the *source_file* operand to
25092 the *destination* specified by the *target_file*. This first synopsis form is assumed when the final
25093 operand does not name an existing directory and is not a symbolic link referring to an existing
25094 directory.

25095 In the second synopsis form, *mv* shall move each file named by a *source_file* operand to a
25096 *destination* file in the existing directory named by the *target_dir* operand, or referenced if
25097 *target_dir* is a symbolic link referring to an existing directory. The *destination* path for each
25098 *source_file* shall be the concatenation of the target directory, a single slash character, and the last
25099 path name component of the *source_file*. This second form is assumed when the final operand
25100 names an existing directory.

25101 If any operand specifies an existing file of a type not specified by the System Interfaces volume |
25102 of IEEE Std. 1003.1-200x, the behavior is implementation-defined. |

25103 For each *source_file* the following steps shall be taken:

25104 1. If the destination path exists, the **–f** option is not specified, and either of the following
25105 conditions is true:

25106 a. The permissions of the destination path do not permit writing and the standard input
25107 is a terminal.

25108 b. The **–i** option is specified.

25109 the *mv* utility shall write a prompt to standard error and read a line from standard input. If |
25110 the response is not affirmative, *mv* shall do nothing more with the current *source_file* and
25111 go on to any remaining *source_file*s.

25112 2. The *mv* utility shall perform actions equivalent to the *rename*( ) function defined in the
25113 System Interfaces volume of IEEE Std. 1003.1-200x, called with the following arguments:

25114 a. The *source_file* operand is used as the *old* argument.

25115 b. The destination path is used as the *new* argument.

25116 If this succeeds, *mv* shall do nothing more with the current *source_file* and go on to any
25117 remaining *source_file*s. If this fails for any reasons other than those described for the *errno*
25118 [EXDEV] in the System Interfaces volume of IEEE Std. 1003.1-200x, *mv* shall write a
25119 diagnostic message to standard error, do nothing more with the current *source_file*, and go
25120 on to any remaining *source_file*s.

25121 3. If the destination path exists, and it is a file of type directory and *source_file* is not a file of
25122 type directory, or it is a file not of type directory and *source_file* is a file of type directory,
25123 *mv* shall write a diagnostic message to standard error, do nothing more with the current
25124 *source_file*, and go on to any remaining *source_file*s.

25125 4. If the destination path exists, *mv* shall attempt to remove it. If this fails for any reason, *mv*
25126 shall write a diagnostic message to standard error, do nothing more with the current
25127 *source_file*, and go on to any remaining *source_file*s.

5. The file hierarchy rooted in *source_file* shall be duplicated as a file hierarchy rooted in the *destination* path. If *source_file* or any of the files below it in the hierarchy are symbolic links, the links themselves shall be duplicated, including their contents, rather than any files to which they refer. The following characteristics of each file in the file hierarchy shall be duplicated:

   - The time of last data modification and time of last access
   - The user ID and group ID
   - The file mode

   If the user ID, group ID, or file mode of a regular file cannot be duplicated, the file mode bits S_ISUID and S_ISGID shall not be duplicated.

   When files are duplicated to another file system, the implementation may require that the process invoking *mv* has read access to each file being duplicated.

   If the duplication of the file hierarchy fails for any reason, *mv* shall write a diagnostic message to standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

   If the duplication of the file characteristics fails for any reason, *mv* shall write a diagnostic message to standard error, but this failure shall not cause *mv* to modify its exit status.

6. The file hierarchy rooted in *source_file* shall be removed. If this fails for any reason, *mv* shall write a diagnostic message to the standard error, do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

OPTIONS

The *mv* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f Do not prompt for confirmation if the destination path exists. Any previous occurrences of the **–i** option is ignored.

–i Prompt for confirmation if the destination path exists. Any previous occurrences of the **–f** option is ignored.

Specifying more than one of the **–f** or **–i** options shall not be considered an error. The last option specified shall determine the behavior of *mv*.

OPERANDS

The following operands shall be supported:

source_file A path name of a file or directory to be moved.

target_file A new path name for the file or directory being moved.

target_dir A path name of an existing directory into which to move the input files.

STDIN

Used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

INPUT FILES

The input files specified by each *source_file* operand can be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mv*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Prompts shall be written to the standard error under the conditions specified in the DESCRIPTION section. The prompts shall contain the *destination* path name, but their format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files may be of any file type.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were moved successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If the copying or removal of *source_file* is prematurely terminated by a signal or error, *mv* may leave a partial copy of *source_file* at the source or destination. The *mv* utility shall not modify both *source_file* and the destination path simultaneously; termination at any point shall leave either *source_file* or the destination path complete.

APPLICATION USAGE

None.

EXAMPLES

If the current directory contains only files **a** (of any type defined by the System Interfaces volume of IEEE Std. 1003.1-200x), **b** (also of any type), and a directory **c**:

```
mv a b c
mv c d
```

results with the original files **a** and **b** residing in the directory **d** in the current directory.

RATIONALE

Early proposals diverged from the SVID and BSD historical practice in that they required that when the destination path exists, the **–f** option is not specified, and input is not a terminal, *mv* fails. This was done for compatibility with *cp*. The current text returns to historical practice. It should be noted that this is consistent with the *rename*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, which does not require write permission on the target.

For absolute clarity, paragraph (1), describing the behavior of *mv* when prompting for confirmation, should be interpreted in the following manner:

```
if (exists AND (NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The **–i** option exists on BSD systems, giving applications and users a way to avoid accidentally unlinking files when moving others. When the standard input is not a terminal, the 4.3 BSD *mv* deletes all existing destination paths without prompting, even when **–i** is specified; this is inconsistent with the behavior of the 4.3 BSD *cp* utility, which always generates an error when the file is unwritable and the standard input is not a terminal. The standard developers decided that use of **–i** is a request for interaction, so when the *destination* path exists, the utility takes instructions from whatever responds to standard input.

The *rename*( ) function is able to move directories within the same file system. Some historical versions of *mv* have been able to move directories, but not to a different file system. The standard developers considered that this was an annoying inconsistency, so this volume of IEEE Std. 1003.1-200x requires directories to be able to be moved even across file systems. There is no **–R** option to confirm that moving a directory is actually intended, since such an option was not required for moving directories in historical practice. Requiring the application to specify it sometimes, depending on the destination, seemed just as inconsistent. The semantics of the *rename*( ) function were preserved as much as possible. For example, *mv* is not permitted to ‘‘rename’’ files to or from directories, even though they might be empty and removable.

Historic implementations of *mv* did not exit with a non-zero exit status if they were unable to duplicate any file characteristics when moving a file across file systems, nor did they write a diagnostic message for the user. The former behavior has been preserved to prevent scripts from breaking; a diagnostic message is now required, however, so that users are alerted that the file characteristics have changed.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the **–f** option or using the **–i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

When *mv* is dealing with a single file system and *source_file* is a symbolic link, the link itself is moved as a consequence of the dependence on the *rename*( ) functionality, per the

DESCRIPTION. Across file systems, this has to be made explicit.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The *mv* utility is changed to describe processing of symbolic links as specified in the IEEE P1003.2b draft standard.

25271 **NAME**

25272 newgrp — change to a new group

25273 **SYNOPSIS**

25274 UP
```
newgrp [-l][group
```
25275

25276 **DESCRIPTION**

25277 The *newgrp* utility shall create a new shell execution environment with a new real and effective
25278 group identification. Of the attributes listed in Section 2.13 (on page 2273), the new shell
25279 execution environment shall retain the working directory, file creation mask, and exported
25280 variables from the previous environment (that is, open files, traps, unexported variables, alias
25281 definitions, shell functions, and *set* options may be lost). All other aspects of the process
25282 environment that are preserved by the *exec* family of functions defined in the System Interfaces
25283 volume of IEEE Std. 1003.1-200x shall also be preserved by *newgrp*; whether other aspects are
25284 preserved is unspecified.

25285 A failure to assign the new group identifications (for example, for security or password-related
25286 reasons) shall not prevent the new shell execution environment from being created.

25287 The *newgrp* utility shall affect the supplemental groups for the process as follows:

25288 • On systems where the effective group ID is normally in the supplementary group list (or
25289 whenever the old effective group ID actually is in the supplementary group list):

25290 — If the new effective group ID is also in the supplementary group list, *newgrp* shall change
25291 the effective group ID.

25292 — If the new effective group ID is not in the supplementary group list, *newgrp* shall add the
25293 new effective group ID to the list, if there is room to add it.

25294 • On systems where the effective group ID is not normally in the supplementary group list (or
25295 whenever the old effective group ID is not in the supplementary group list):

25296 — If the new effective group ID is in the supplementary group list, *newgrp* shall delete it.

25297 — If the old effective group ID is not in the supplementary list, *newgrp* shall add it if there is
25298 room.

25299 **Note:** The System Interfaces volume of IEEE Std. 1003.1-200x does not specify whether the
25300 effective group ID of a process is included in its supplementary group list.

25301 With no operands, *newgrp* shall change the effective group back to the groups identified in the
25302 user's user entry, and shall set the list of supplementary groups to that set in the user's group
25303 database entries.

25304 If a password is required for the specified group, and the user is not listed as a member of that
25305 group in the group database, the user shall be prompted to enter the correct password for that
25306 group. If the user is listed as a member of that group, no password is requested. If no password
25307 is required for the specified group, it is implementation-defined whether users not listed as
25308 members of that group can change to that group. Whether or not a password is required,
25309 implementation-defined system accounting or security mechanisms may impose additional
25310 authorization restrictions that may cause *newgrp* to write a diagnostic message and suppress the
25311 changing of the group identification.

25312 **OPTIONS**

25313 The *newgrp* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
25314 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–l (The letter ell.) Change the environment to what would be expected if the user actually logged in again.

OPERANDS

The following operand shall be supported:

group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs shall be set. If *group* is a non-negative numeric string and exists in the group database as a group name (see *getgrnam*( )), the numeric group ID associated with that group name shall be used as the group ID.

STDIN

Not used.

INPUT FILES

The file **/dev/tty** shall be used to read a single line of text for password checking, when one is required.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *newgrp*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used for diagnostic messages and a prompt string for a password, if one is required. Diagnostic messages may be written in cases where the exit status is not available. See the EXIT STATUS section.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *newgrp* succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status shall be the exit status of the shell. Otherwise, the following exit value shall be returned:

>0 An error occurred.

CONSEQUENCES OF ERRORS

The invoking shell may terminate.

APPLICATION USAGE

There is no convenient way to enter a password into the Group Database. Use of group passwords is not encouraged, because by their very nature they encourage poor security practices. Group passwords may disappear in the future.

A common implementation of *newgrp* is that the current shell uses *exec* to overlay itself with *newgrp*, which in turn overlays itself with a new shell after changing group. On some systems, however, this may not occur and *newgrp* may be invoked as a subprocess.

The *newgrp* command is intended only for use from an interactive terminal. It does not offer a useful interface for the support of applications.

The exit status of *newgrp* is generally inapplicable. If *newgrp* is used in a script, in most cases it successfully invokes a new shell and the rest of the original shell script is bypassed when the new shell exits. Used interactively, *newgrp* displays diagnostic messages to indicate problems. But usage such as:

```
newgrp foo
echo $?
```

is not useful because the new shell might not have access to any status *newgrp* may have generated (and most historical systems do not provide this status). A zero status echoed here does not necessarily indicate that the user has changed to the new group successfully. Following *newgrp* with the *id* command provides a portable means of determining whether the group change was successful or not.

EXAMPLES

None.

RATIONALE

Most historical implementations use one of the *exec* functions to implement the behavior of *newgrp*. Errors detected before the *exec* leave the environment unchanged, while errors detected after the *exec* leave the user in a changed environment. While it would be useful to have *newgrp* issue a diagnostic message to tell the user that the environment changed, it would be inappropriate to require this change to some historical implementations.

The password mechanism is allowed in the group database, but how this would be implemented is not specified.

The *newgrp* utility was retained in this volume of IEEE Std. 1003.1-200x, even given the existence of the multiple group permissions feature in the System Interfaces volume of IEEE Std. 1003.1-200x, for several reasons. First, in some systems, the group ownership of a newly created file is determined by the group of the directory in which the file is created, as allowed by the System Interfaces volume of IEEE Std. 1003.1-200x; on other systems, the group ownership of a newly created file is determined by the effective group ID. On systems of the latter type, *newgrp* allows files to be created with a specific group ownership. Finally, many

systems use the real group ID in accounting, and on such systems, *newgrp* allows the accounting identity of the user to be changed.

FUTURE DIRECTIONS

None.

sh, the System Interfaces volume of IEEE Std. 1003.1-200x, *exec*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

The *newgrp* utility is now mandatory; it is optional in Issue 3.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The text describing supplemental groups is no longer conditional on {NGROUPS_MAX} being greater than 1. This is because {NGROUPS_MAX} now has a minimum value of 8. This is a FIPS requirement.

25419 **NAME**

25420 nice — invoke a utility with an altered nice value

25421 **SYNOPSIS**

25422 UP
```
nice [–n increment] utility [argument...]
```
25423

25424 **DESCRIPTION**

25425 The *nice* utility shall invoke a utility, requesting that it be run with a different nice value (see the
25426 Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.241, Nice Value). With no options
25427 and only if the user has appropriate privileges, the executed utility shall be run with a nice value
25428 that is some implementation-defined quantity less than or equal to the nice value of the current
25429 process. If the user lacks appropriate privileges to affect the nice value in the requested manner,
25430 the *nice* utility shall not affect the nice value; in this case, a warning message may be written to
25431 standard error, but this shall not prevent the invocation of *utility* or affect the exit status.

25432 **OPTIONS**

25433 The *nice* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
25434 12.2, Utility Syntax Guidelines.

25435 The following option is supported:

25436 **–n** *increment* Specify how the nice value of the executed utility shall be adjusted. The *increment*
25437 option-argument shall be a positive or negative decimal integer that shall be used
25438 to modify the nice value of the executed utility in an implementation-defined
25439 manner.

25440 Positive *increment* values shall cause a lower or unchanged nice value. Negative
25441 *increment* values may require appropriate privileges and shall cause a higher or
25442 unchanged nice value.

25443 The nice value shall be bounded in an implementation-defined manner. If the
25444 requested *increment* would raise or lower the nice value of the executed utility
25445 beyond implementation-defined limits, then the limit whose value was exceeded
25446 shall be used.

25447 **OPERANDS**

25448 The following operands shall be supported:

25449 *utility* The name of a utility that is to be invoked. If the *utility* operand names any of the
25450 special built-in utilities in Section 2.15 (on page 2276), the results are undefined.

25451 *argument* Any string to be supplied as an argument when invoking the utility named by the
25452 *utility* operand.

25453 **STDIN**

25454 Not used.

25455 **INPUT FILES**

25456 None.

25457 **ENVIRONMENT VARIABLES**

25458 The following environment variables shall affect the execution of *nice*:

25459 *LANG* Provide a default value for the internationalization variables that are unset or null.
25460 If *LANG* is unset or null, the corresponding value from the implementation-
25461 defined default locale shall be used. If any of the internationalization variables
25462 contains an invalid setting, the utility shall behave as if none of the variables had
25463 been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path used to locate the utility to be invoked. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If the *utility* utility is invoked, the exit status of *nice* shall be the exit status of *utility*; otherwise, the *nice* utility shall exit with one of the following values:

1-125 An error occurred in the *nice* utility.
126 The utility specified by *utility* was found but could not be invoked.
127 The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The only guaranteed portable uses of this utility are:

nice utility
Run *utility* with the default lower nice value.

nice **–n** <*positive integer*> *utility*
Run *utility* with a lower nice value.

On some systems they have no discernible effect on the invoked utility and on some others they are exactly equivalent.

Historical systems have frequently supported the <*positive integer*> up to 20. Since there is no error penalty associated with guessing a number that is too high, users without access to the system conformance document (to see what limits are actually in place) could use the historical 1 to 20 range or attempt to use very large numbers if the job should be truly low priority.

The nice value value of a process can be displayed using the command:

```
ps –o nice
```

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish ''failure to find a utility'' from ''invoked utility exited with an error indication''. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for ''normal error conditions'' and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

None.

RATIONALE

Due to the text about the limits of the nice value being implementation-defined, *nice* is not actually required to change the nice value of the executed command; the limits could be zero differences from the system default, although the implementor is required to document this fact in the conformance document.

The 4.3 BSD version of *nice* does not check if *increment* is a valid decimal integer. The command *nice* –**x** *utility*, for example, would be treated the same as the command *nice* ––**1** *utility*. If the user does not have appropriate privileges, this results in a ''permission denied'' error. This is considered a bug.

When a user without appropriate privileges gives a negative *increment*, System V treats it like the command *nice* –**0** *utility*, while 4.3 BSD writes a ''permission denied'' message and does not run the utility. Neither was considered clearly superior, so the behavior was left unspecified.

The C shell has a built-in version of *nice* that has a different interface from the one described in this volume of IEEE Std. 1003.1-200x.

The term ''utility'' is used, rather than ''command'', to highlight the fact that shell compound commands, pipelines, and so on, cannot be used. Special built-ins also cannot be used. However, ''utility'' includes user application programs and shell scripts, not just utilities defined in this volume of IEEE Std. 1003.1-200x.

Historical implementations of *nice* provide a nice value range of 40 or 41 discrete steps, with the default nice value being the midpoint of that range. By default, they lower the nice value of the executed utility by 10.

Some historical documentation states that the *increment* value must be within a fixed range. This is misleading; the valid *increment* values on any invocation are determined by the current process nice value, which is not always the default.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in POSIX.4 make the notion of a single underlying priority for all scheduling policies problematic. Some systems may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std. 1003.1-200x, and others may have no effect at all. Because of the use of ''implementation-defined'' in *nice* and *renice*, a wide range of implementation strategies are possible.

25558 This utility is now marked as part of the User Portability Utilities option.

25559 The obsolescent SYNOPSIS is removed.

NAME

nl — line numbering filter

SYNOPSIS

XSI
```
nl [–p][–b type][–d delim][–f type][–h type][–i incr][–l num][–n format]
    [–s sep][–v startnum][–w width][file]
```

DESCRIPTION

The *nl* utility shall read lines from the named *file* or the standard input if no *file* is named and shall reproduce the lines to standard output. Lines shall be numbered on the left. Additional functionality may be provided in accordance with the command options in effect.

The *nl* utility views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (for example, no numbering of header and footer lines while numbering blank lines only in the body).

The starts of logical page sections are signaled by input lines containing nothing but the following delimiter characters:

Line	Start of
`\:\:\:`	Header
`\:\:`	Body
`\:`	Footer

Unless otherwise specified, *nl* assumes the text being read is in a single logical page body.

OPTIONS

The *nl* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines. Only one file can be named.

The following options shall be supported:

–b *type* Specify which logical page body lines shall be numbered. Recognized *types* and their meaning are:

- **a** Number all lines.
- **t** Number only non-empty lines.
- **n** No line numbering.
- **p***string* Number only lines that contain the basic regular expression specified in *string*.

The default *type* for logical page body is **t** (text lines numbered).

–d *delim* Specify the delimiter characters that indicate the start of a logical page section. These can be changed from the default characters `"\:"` to two user-specified characters. If only one character is entered, the second character remains the default character `':'`.

–f *type* Specify the same as **b** *type* except for footer. The default for logical page footer is **n** (no lines numbered).

–h *type* Specify the same as **b** *type* except for header. The default *type* for logical page header is **n** (no lines numbered).

25602 **–i** *incr* Specify the increment value used to number logical page lines. The default is 1.

25603 **–l** *num* Specify the number of blank lines to be considered as one. For example, **–l 2** results
25604 in only the second adjacent blank line being numbered (if the appropriate **–h a**,
25605 **–b a**, or **–f a** option is set). The default is 1.

25606 **–n** *format* Specify the line numbering format. Recognized values are: **ln**, left justified, leading
25607 zeros suppressed; **rn**, right justified, leading zeros suppressed; **rz**, right justified,
25608 leading zeros kept. The default *format* is **rn** (right justified).

25609 **–p** Specify that numbering should not be restarted at logical page delimiters.

25610 **–s** *sep* Specify the characters used in separating the line number and the corresponding
25611 text line. The default *sep* is a <tab>.

25612 **–v** *startnum* Specify the initial value used to number logical page lines. The default is 1.

25613 **–w** *width* Specify the number of characters to be used for the line number. The default *width*
25614 is 6.

25615 **OPERANDS**

25616 The following operand shall be supported:

25617 *file* A path name of a text file to be line-numbered.

25618 **STDIN**

25619 The standard input is a text file that is used if no *file* operand is given.

25620 **INPUT FILES**

25621 The input file named by the *file* operand is a text file.

25622 **ENVIRONMENT VARIABLES**

25623 The following environment variables shall affect the execution of *nl*:

25624 *LANG* Provide a default value for the internationalization variables that are unset or null.
25625 If *LANG* is unset or null, the corresponding value from the implementation-
25626 defined default locale shall be used. If any of the internationalization variables
25627 contains an invalid setting, the utility shall behave as if none of the variables had
25628 been defined.

25629 *LC_ALL* If set to a non-empty string value, override the values of all the other
25630 internationalization variables.

25631 *LC_COLLATE*
25632 Determine the locale for the behavior of ranges, equivalence classes and multi-
25633 character collating elements within regular expressions.

25634 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
25635 characters (for example, single-byte as opposed to multi-byte characters in
25636 arguments and input files), the behavior of character classes within regular
25637 expressions, and for deciding which characters are in character class **graph** (for the
25638 **–b t**, **–f t**, and **–h t** options).

25639 *LC_MESSAGES*
25640 Determine the locale that should be used to affect the format and contents of
25641 diagnostic messages written to standard error.

25642 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

25643 **ASYNCHRONOUS EVENTS**
25644 Default.

25645 **STDOUT**
25646 The standard output shall be a text file in the following format:

25647 `"%s%s%s", <line number>, <separator>, <input line>`

25648 where <*line number*> is one of the following numeric formats:

25649 `%6d` When the **rn** format is used (the default; see –**n**).

25650 `%06d` When the **rz** format is used.

25651 `%–6d` When the *ln* format is used.

25652 <empty> When line numbers are suppressed for a portion of the page; the <*separator*> is also
25653 suppressed.

25654 In the preceding list, the number 6 is the default width; the –**w** option can change this value.

25655 **STDERR**
25656 Used only for diagnostic messages.

25657 **OUTPUT FILES**
25658 None.

25659 **EXTENDED DESCRIPTION**
25660 None.

25661 **EXIT STATUS**
25662 The following exit values shall be returned:

25663 0 Successful completion.

25664 >0 An error occurred.

25665 **CONSEQUENCES OF ERRORS**
25666 Default.

25667 **APPLICATION USAGE**
25668 In using the –**d** *delim* option, care should be taken to escape characters that have special meaning
25669 to the command interpreter.

25670 **EXAMPLES**
25671 The command:

25672 `nl –v 10 –i 10 –d \!+ file1`

25673 numbers *file1* starting at line number 10 with an increment of 10. The logical page delimiter is
25674 `"!+"`. Note that the `'!'` has to be escaped when using *csh* as a command interpreter because of
25675 its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but does not do any
25676 harm.

25677 **RATIONALE**
25678 None.

25679 **FUTURE DIRECTIONS**
25680 None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Utility Syntax Guideline support mandated.

Internationalized environment variable support mandated.

Issue 5

The option [**–f** *type*] is added to the SYNOPSIS. The option descriptions are presented in alphabetic order. The description of **–bt** is changed to ‘‘Number only non-empty lines’’.

Issue 6

The obsolescent behavior allowing the options to be intermingled with the optional *file* operand is removed.

NAME

nm — write the name list of an object file (**DEVELOPMENT**)

SYNOPSIS

UP SD XSI `nm [–APv][–efox][ –g| –u][–t format] file...`

DESCRIPTION

This utility shall be provided on systems that support both the User Portability Utilities option and the Software Development Utilities option. On other systems it is optional. Certain options are only available on XSI-conformant systems.

The *nm* utility shall display symbolic information appearing in the object file, executable file or object-file library named by *file*. If no symbolic information is available for a valid input file, the *nm* utility shall report that fact, but not consider it an error condition.

XSI The default base used when numeric values are written is unspecified. On XSI-conformant systems, it shall be decimal.

OPTIONS

The *nm* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–A Write the full path name or library name of an object on each line.

XSI **–e** Write only external (global) and static symbol information.

XSI **–f** Produce full output. Write redundant symbols (**.text**, **.data**, and **.bss**), normally suppressed.

–g Write only external (global) symbol information.

XSI **–o** Write numeric values in octal (equivalent to **–t o**).

–P Write information in a portable output format, as specified in the STDOUT section.

–t *format* Write each numeric value in the specified format. The format shall be dependent on the single character used as the *format* option-argument:

XSI d The offset is written in decimal (default).

o The offset is written in octal.

x The offset is written in hexadecimal.

–u Write only undefined symbols.

–v Sort output by value instead of alphabetically.

XSI **–x** Write numeric values in hexadecimal (equivalent to **–t x**).

OPERANDS

The following operand shall be supported:

file A path name of an object file, executable file, or object-file library.

STDIN

See the INPUT FILES section.

INPUT FILES

The input file shall be an object file, an object-file library whose format is the same as those produced by the *ar* utility for link editing, or an executable file. The *nm* utility may accept additional implementation-defined object library formats for the input file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nm*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for character collation information for the symbol-name and symbol-value collation sequences.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If symbolic information is present in the input files, then for each file or for each member of an archive, the *nm* utility shall write the following information to standard output. By default, the format is unspecified, but the output shall be sorted alphabetically by symbol name:

- Library or object name, if **–A** is specified
- Symbol name
- Symbol type, which shall either be one of the following single characters or an implementation-defined type represented by a single character:

  `A` Global absolute symbol.

  `a` Local absolute symbol.

  `B` Global ‘‘bss’’ (that is, uninitialized data space) symbol.

  `b` Local bss symbol.

  `D` Global data symbol.

  `d` Local data symbol.

  `T` Global text symbol.

  `t` Local text symbol.

25774 U Undefined symbol.

25775 • Value of the symbol

25776 • The size associated with the symbol, if applicable

25777 This information may be supplemented by additional information specific to the
25778 implementation.

25779 If the **–P** option is specified, the previous information shall be displayed using the following
25780 portable format. The three versions differ depending on whether **–t d**, **–t o**, or **–t x** was specified,
25781 respectively:

25782 `"%s%s %s %d %d\n", <library/object name>, <name>, <type>,`
25783 `<value>, <size>`

25784 `"%s%s %s %o %o\n", <library/object name>, <name>, <type>,`
25785 `<value>, <size>`

25786 `"%s%s %s %x %x\n", <library/object name>, <name>, <type>,`
25787 `<value>, <size>`

25788 where

25789 <*library/object name*> shall be formatted as follows:

25790 • If **–A** is not specified, <*library/object name*> shall be an empty string.

25791 • If **–A** is specified and the corresponding *file* operand does not name a library:

25792 `"%s: ", <file>`

25793 • If **–A** is specified and the corresponding *file* operand names a library. In this case, <*object file*>
25794 shall name the object file in the library containing the symbol being described:

25795 `"%s[%s]: ", <file>, <object file>`

25796 If **–A** is not specified, then if more than one *file* operand is specified or if only one *file* operand is
25797 specified and it names a library, *nm* shall write a line identifying the object containing the
25798 following symbols before the lines containing those symbols, in the form:

25799 • If the corresponding *file* operand does not name a library:

25800 `"%s:\n", <file>`

25801 • If the corresponding *file* operand names a library; in this case, <*object file*> shall be the name
25802 of the file in the library containing the following symbols:

25803 `"%s[%s]:\n", <file>, <object file>`

25804 If **–P** is specified, but **–t** is not, the format shall be as if **–t x** had been specified.

25805 **STDERR**

25806 Used only for diagnostic messages.

25807 **OUTPUT FILES**

25808 None.

25809 **EXTENDED DESCRIPTION**

25810 None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Mechanisms for dynamic linking make this utility less meaningful when applied to an executable file because a dynamically linked executable may omit numerous library routines that would be found in a statically linked executable.

EXAMPLES

None.

RATIONALE

Historical implementations of *nm* have used different bases for numeric output and supplied different default types of symbols that were reported. The **–t** *format* option, similar to that used in *od* and *strings*, can be used to specify the numeric base; **–g** and **–u** can be used to restrict the amount of output or the types of symbols included in the output.

The option list was significantly reduced from that provided by historical implementations.

The *nm* description is a subset of both the System V and BSD *nm* utilities with no specified default output.

It was recognized that mechanisms for dynamic linking make this utility less meaningful when applied to an executable file (because a dynamically linked executable file may omit numerous library routines that would be found in a statically linked executable file), but the value of *nm* during software development was judged to outweigh other limitations.

The compromise of using **–t** *format versus* using **–d**, **–o**, and other similar options was necessary because of differences in the meaning of **–o** between implementations. The **–o** option from BSD has been provided here as **–A** to avoid confusion with the **–o** from System V (which has been provided here as **–t** and as **–o** on XSI-conformant systems).

The default output format of *nm* is not specified because of differences in historical implementations. The **–P** option was added to allow some type of portable output format. After a comparison of the different formats used in SunOS, BSD, SVR3, and SVR4, it was decided to create one that did not match the current format of any of these four systems. The format devised is easy to parse by humans, easy to parse in shell scripts, and does not need to vary depending on locale (because no English descriptions are included). All of the systems currently have the information available to use this format.

The format given in *nm* STDOUT uses spaces between the fields, which may be any number of <blank>s required to align the columns. The single-character types were selected to match historical practice, and the requirement that implementation additions also be single characters made parsing the information easier for shell scripts.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

This utility is now marked as supported when both the User Portability Utilities option and the Software Development Utilities option are supported.

25861 **NAME**

25862 nohup — invoke a utility immune to hangups

25863 **SYNOPSIS**

25864 nohup *utility* **[***argument...***]**

25865 **DESCRIPTION**

25866 The *nohup* utility shall invoke the utility named by the *utility* operand with arguments supplied
25867 as the *argument* operands. At the time the named *utility* is invoked, the SIGHUP signal shall be
25868 set to be ignored.

25869 If the standard output is a terminal, all output written by the named *utility* to its standard output
25870 shall be appended to the end of the file **nohup.out** in the current directory. If **nohup.out** cannot
25871 be created or opened for appending, the output shall be appended to the end of the file
25872 **nohup.out** in the directory specified by the *HOME* environment variable. If neither file can be
25873 created or opened for appending, *utility* shall not be invoked. If a file is created, the file's
25874 permission bits shall be set to S_IRUSR | S_IWUSR.

25875 If the standard error is a terminal, all output written by the named *utility* to its standard error
25876 shall be redirected to the same file descriptor as the standard output.

25877 **OPTIONS**

25878 None.

25879 **OPERANDS**

25880 The following operands shall be supported:

25881 *utility* The name of a utility that is to be invoked. If the *utility* operand names any of the
25882 special built-in utilities in Section 2.15 (on page 2276), the results are undefined.

25883 *argument* Any string to be supplied as an argument when invoking the utility named by the
25884 *utility* operand.

25885 **STDIN**

25886 Not used.

25887 **INPUT FILES**

25888 None.

25889 **ENVIRONMENT VARIABLES**

25890 The following environment variables shall affect the execution of *nohup*:

25891 *HOME* Determine the path name of the user's home directory: if the output file **nohup.out**
25892 cannot be created in the current directory, the *nohup* utility shall use the directory
25893 named by *HOME* to create the file.

25894 *LANG* Provide a default value for the internationalization variables that are unset or null.
25895 If *LANG* is unset or null, the corresponding value from the implementation-
25896 defined default locale shall be used. If any of the internationalization variables
25897 contains an invalid setting, the utility behav se as if none of the variables had been
25898 defined.

25899 *LC_ALL* If set to a non-empty string value, override the values of all the other
25900 internationalization variables.

25901 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
25902 characters (for example, single-byte as opposed to multi-byte characters in
25903 arguments).

25904 *LC_MESSAGES*
25905 Determine the locale that should be used to affect the format and contents of
25906 diagnostic messages written to standard error.

25907 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

25908 *PATH* Determine the search path that is used to locate the utility to be invoked. See the |
25909 Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment |
25910 Variables. |

25911 **ASYNCHRONOUS EVENTS**
25912 The *nohup* utility shall take the standard action for all signals except that SIGHUP shall be
25913 ignored.

25914 **STDOUT**
25915 If the standard output is not a terminal, the standard output of *nohup* shall be the standard
25916 output generated by the execution of the *utility* specified by the operands. Otherwise, nothing
25917 shall be written to the standard output.

25918 **STDERR**
25919 If the standard output is a terminal, a message shall be written to the standard error, indicating
25920 the name of the file to which the output is being appended. The name of the file shall be either
25921 **nohup.out** or **$HOME/nohup.out**.

25922 **OUTPUT FILES**
25923 If the standard output is a terminal, all output written by the named *utility* to the standard
25924 output and standard error is appended to the file **nohup.out**, which is created if it does not
25925 already exist.

25926 **EXTENDED DESCRIPTION**
25927 None.

25928 **EXIT STATUS**
25929 The following exit values shall be returned:

25930 126 The utility specified by *utility* was found but could not be invoked.

25931 127 An error occurred in the *nohup* utility or the utility specified by *utility* could not be
25932 found.

25933 Otherwise, the exit status of *nohup* shall be that of the utility specified by the *utility* operand.

25934 **CONSEQUENCES OF ERRORS**
25935 Default.

25936 **APPLICATION USAGE**
25937 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if
25938 an error occurs so that applications can distinguish ‘‘failure to find a utility’’ from ‘‘invoked
25939 utility exited with an error indication’’. The value 127 was chosen because it is not commonly
25940 used for other meanings; most utilities use small values for ‘‘normal error conditions’’ and the
25941 values above 128 can be confused with termination due to receipt of a signal. The value 126 was
25942 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
25943 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
25944 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
25945 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
25946 any other reason.

25947 **EXAMPLES**

25948 It is frequently desirable to apply *nohup* to pipelines or lists of commands. This can be done by
25949 placing pipelines and command lists in a single file; this file can then be invoked as a utility, and
25950 the *nohup* applies to everything in the file.

25951 Alternatively, the following command can be used to apply *nohup* to a complex command:

25952 `nohup sh –c 'complex-command-line'`

25953 **RATIONALE**

25954 The 4.3 BSD version ignores SIGTERM and SIGHUP, and if **./nohup.out** cannot be used, it fails
25955 instead of trying to use **$HOME/nohup.out**.

25956 The *csh* utility has a built-in version of *nohup* that acts differently from the POSIX Shell and
25957 Utilities *nohup*.

25958 The term *utility* is used, rather than *command*, to highlight the fact that shell compound
25959 commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility*
25960 includes user application programs and shell scripts, not just the standard utilities.

25961 Historical versions of the *nohup* utility use default file creation semantics. Some more recent
25962 versions use the permissions specified here as an added security precaution.

25963 Some historical implementations ignore SIGQUIT in addition to SIGHUP; others ignore
25964 SIGTERM. An early proposal allowed, but did not require, SIGQUIT to be ignored. Several
25965 reviewers objected that *nohup* should only modify the handling of SIGHUP as required by this
25966 volume of IEEE Std. 1003.1-200x.

25967 **FUTURE DIRECTIONS**

25968 None.

25971 **CHANGE HISTORY**

25972 First released in Issue 2.

25973 **Issue 4**

25974 Aligned with the ISO / IEC 9945-2: 1993 standard.

25975 **NAME**

25976 od — dump files in various formats

25977 **SYNOPSIS**

25978 `od [–v][–A` *address_base*`][–j` *skip*`][–N` *count*`][–t` *type_string*`]...`

25979 `[`*file*`...]`

25980 XSI `od [–bcdosx][`*file*`] [[+]`*offset*`[.][b]]`

25981

25982 **DESCRIPTION**

25983 The *od* utility shall write the contents of its input files to standard output in a user-specified
25984 format.

25985 **OPTIONS**

25986 The *od* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, |
25987 XSI Utility Syntax Guidelines, except that the order of presentation of the **–t** options and the |
25988 **–bcdosx** options is significant.

25989 The following options shall be supported:

25990 **–A** *address_base*

25991 Specify the input offset base. See the EXTENDED DESCRIPTION section. The
25992 application shall ensure that the *address_base* option-argument is a character. The
25993 characters `'d'`, `'o'`, and `'x'` specify that the offset base shall be written in
25994 decimal, octal, or hexadecimal, respectively. The character `'n'` specifies that the
25995 offset shall not be written.

25996 XSI **–b** Interpret bytes in octal. This is equivalent to **–t o1**.

25997 XSI **–c** Interpret bytes as characters specified by the current setting of the *LC_CTYPE*
25998 category. Certain non-graphic characters appear as C escapes: `"NUL=\0"`,
25999 `"BS=\b"`, `"FF=\f"`, `"NL=\n"`, `"CR=\r"`, `"HT=\t"`; others appear as 3-digit octal
26000 numbers.

26001 XSI **–d** Interpret *word*s (two-byte units) in unsigned decimal. This is equivalent to **–t u2**.

26002 **–j** *skip* Jump over *skip* bytes from the beginning of the input. The *od* utility shall read or
26003 seek past the first *skip* bytes in the concatenated input files. If the combined input
26004 is not at least *skip* bytes long, the *od* utility shall write a diagnostic message to
26005 standard error and exit with a non-zero exit status.

26006 By default, the *skip* option-argument shall be interpreted as a decimal number.
26007 With a leading `"0x"` or `"0X"`, the offset shall be interpreted as a hexadecimal
26008 number; otherwise, with a leading `'0'`, the offset shall be interpreted as an octal
26009 number. Appending the character `'b'`, `'k'`, or `'m'` to offset shall cause it to be
26010 MAN interpreted as a multiple of 512, 1 024, or 1 048 576 bytes, respectively. If the *skip* |
26011 number is hexadecimal, any appended `'b'` shall be considered to be the final
26012 hexadecimal digit.

26013 **–N** *count* Format no more than *count* bytes of input. By default, *count* shall be interpreted as
26014 a decimal number. With a leading `"0x"` or `"0X"`, *count* shall be interpreted as a
26015 hexadecimal number; otherwise, with a leading `'0'`, it shall be interpreted as an
26016 octal number. If *count* bytes of input (after successfully skipping, if **–j** *skip* is
26017 specified) are not available, it shall not be considered an error; the *od* utility shall
26018 format the input that is available.

26019 XSI **–o** Interpret *word*s (two-byte units) in octal. This is equivalent to **–t o2**.

XSI **–s** Interpret *word*s (two-byte units) in signed decimal. This is equivalent to **–t d2**.

–t *type_string*

Specify one or more output types. See the EXTENDED DESCRIPTION section. The application shall ensure that the *type_string* option-argument is a string specifying the types to be used when writing the input data. The string shall consist of the type specification characters **a**, **c**, **d**, **f**, **o**, **u**, and **x**, specifying named character, character, signed decimal, floating point, octal, unsigned decimal, and hexadecimal, respectively. The type specification characters **d**, **f**, **o**, **u**, and **x** can be followed by an optional unsigned decimal integer that specifies the number of bytes to be transformed by each instance of the output type. The type specification character **f** can be followed by an optional **F**, **D**, or **L** indicating that the conversion should be applied to an item of type **float**, **double**, or **long double**, respectively. The type specification characters **d**, **o**, **u** and **x** can be followed by an optional **C**, **S**, **I**, or **L** indicating that the conversion should be applied to an item of type **char**, **short**, **int**, or **long**, respectively. Multiple types can be concatenated within the same *type_string* and multiple **–t** options can be specified. Output lines shall be written for each type specified in the order in which the type specification characters are specified.

–v Write all input data. Without the **–v** option, any number of groups of output lines, which would be identical to the immediately preceding group of output lines (except for the byte offsets), shall be replaced with a line containing only an asterisk (`'*'`).

XSI **–x** Interpret *word*s (two-byte units) in hexadecimal. This is equivalent to **–t x2**.

XSI Multiple types can be specified by using multiple **–bcdostx** options. Output lines are written for each type specified in the order in which the types are specified.

OPERANDS

The following operands shall be supported:

file A path name of a file to be read. If no *file* operands are specified, the standard input shall be used. If the first character of *file* is a plus sign (`'+'`) or the first character of the first *file* operand is numeric, no more than two operands are given, and none of the **–A**, **–j**, **–N**, or **–t** options is specified, the results are unspecified. On XSI-conformant systems, the operand shall be assumed to be an *offset*.

XSI **[+]***offset***[.][b]**

The *offset* operand specifies the offset in the file where dumping is to commence. This operand is normally interpreted as octal bytes. If `'.'` is appended, the offset shall be interpreted in decimal. If `'b'` is appended, the offset shall be interpreted in units of 512 bytes. If the *file* argument is omitted, and none of the **–A**, **–j**, **–N**, or **–t** options is specified, the application shall ensure that the offset argument is preceded by `'+'`.

STDIN

The standard input shall be used only if no *file* operands are specified. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *od*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the locale for selecting the radix character used when writing floating-point formatted output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the EXTENDED DESCRIPTION section.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *od* utility shall copy sequentially each input file to standard output, transforming the input
XSI data according to the output types specified by the **–t** options or the **–bcdosx** options. If no output type is specified, the default output shall be as if **–t oS** had been specified.

The number of bytes transformed by the output type specifier **c** may be variable depending on the *LC_CTYPE* category.

The default number of bytes transformed by output type specifiers **d**, **f**, **o**, **u**, and **x** corresponds to the various C-language types as follows. If the *c99* compiler is present on the system, these specifiers shall correspond to the sizes used by default in that compiler. Otherwise, these sizes may vary among systems that conform to IEEE Std. 1003.1-200x.

- For the type specifier characters **d**, **o**, **u**, and **x**, the default number of bytes shall correspond to the size of the underlying implementation's basic integer type. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **char**, **short**, **int**, and **long**. These numbers can also be specified by an application as the characters `'C'`, `'S'`, `'I'`, and `'L'`, respectively.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 99: We need to address long long, which usually uses the notation LL; however, that is 2 characters. Do we need to invent a new single character notation for long long?

The implementation shall also support the values 1, 2, and 4, even if it provides no C-Language types of those sizes. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.

- For the type specifier character **f**, the default number of bytes shall correspond to the number of bytes in the underlying implementation's basic double precision floating-point data type. The implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **float, double**, and **long double**. These numbers can also be specified by an application as the characters `'F'`, `'D'`, and `'L'`, respectively.

The type specifier character **a** specifies that bytes are interpreted as named characters from the International Reference Version (IRV) of the ISO/IEC 646:1991 standard. Only the least significant seven bits of each byte shall be used for this type specification. Bytes with the values listed in the following table shall be written using the corresponding names for those characters.

Table 4-12 Named Characters in *od*

Value	Name	Value	Name	Value	Name	Value	Name
\000	**nul**	\001	**soh**	\002	**stx**	\003	**etx**
\004	**eot**	\005	**enq**	\006	**ack**	\007	**bel**
\010	**bs**	\011	**ht**	\012	**lf** or **nl***	\013	**vt**
\014	**ff**	\015	**cr**	\016	**so**	\017	**si**
\020	**dle**	\021	**dc1**	\022	**dc2**	\023	**dc3**
\024	**dc4**	\025	**nak**	\026	**syn**	\027	**etb**
\030	**can**	\031	**em**	\032	**sub**	\033	**esc**
\034	**fs**	\035	**gs**	\036	**rs**	\037	**us**
\040	**sp**	\177	**del**				

Note: The `"\012"` value may be written either as **lf** or **nl**.

The type specifier character **c** specifies that bytes are interpreted as characters specified by the current setting of the *LC_CTYPE* locale category. Characters listed in the table in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`"\\"`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequences, except that backslash shall be written as a single backslash and a NUL shall be written as `'\0'`. Other non-printable characters shall be written as one three-digit octal number for each byte in the character. If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation-defined. Printable multi-byte characters shall be written in the area corresponding to the first byte of the character; the two-character sequence `"**"` shall be written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. When either the **–j** *skip* or **–N** *count* option is specified along with the **c** type specifier, and this results in an attempt to start or finish in the middle of a multi-byte character, the result is implementation-defined.

The input data shall be manipulated in blocks, where a block is defined as a multiple of the least common multiple of the number of bytes transformed by the specified output types. If the least

common multiple is greater than 16, the results are unspecified. Each input block shall be written as transformed by each output type, one per written line, in the order that the output types were specified. If the input block size is larger than the number of bytes transformed by the output type, the output type shall sequentially transform the parts of the input block, and the output from each of the transformations shall be separated by one or more <blank> characters.

If, as a result of the specification of the **–N** option or end-of-file being reached on the last input file, input data only partially satisfies an output type, the input shall be extended sufficiently with null bytes to write the last byte of the input.

Unless **–A n** is specified, the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written. The format of the input offset is unspecified; however, it shall not contain any <blank> characters, shall start at the first character of the output line, and shall be followed by one or more <blank> characters. In addition, the offset of the byte following the last byte written shall be written after all the input data has been processed, but shall not be followed by any <blank> characters.

If no **–A** option is specified, the input offset base is unspecified.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Applications are warned not to use file names starting with `'+'` or a first operand starting with a numeric character so that the old functionality can be maintained by implementations, unless they specify one of the new options specified by the ISO/IEC 9945-2:1993 standard. To guarantee that one of these file names is always interpreted as a file name, an application could always specify the address base format with the **–A** option.

EXAMPLES

If a file containing 128 bytes with decimal values zero to 127, in increasing order, is supplied as standard input to the command:

```
od –A d –t a
```

on an implementation using an input block size of 16 bytes, the standard output, independent of the current locale setting, would be similar to:

```
0000000 nul soh stx etx eot enq ack bel  bs  ht  nl  vt  ff  cr  so  si
0000016 dle dc1 dc2 dc3 dc4 nak syn etb can  em sub esc  fs  gs  rs  us
0000032  sp   !   "   #   $   %   &   ’   (   )   *   +   ,   –   .   /
0000048   0   1   2   3   4   5   6   7   8   9   :   ;   <   =   >   ?
0000064   @   A   B   C   D   E   F   G   H   I   J   K   L   M   N   O
0000080   P   Q   R   S   T   U   V   W   X   Y   Z   [   \   ]   ^   _
0000096   ‘   a   b   c   d   e   f   g   h   i   j   k   l   m   n   o
0000112   p   q   r   s   t   u   v   w   x   y   z   {   |   }   ~ del
0000128
```

Note that this volume of IEEE Std. 1003.1-200x allows **nl** or **lf** to be used as the name for the ISO/IEC 646:1991 standard IRV character with decimal value 10. The IRV names this character **lf** (line feed), but traditional implementations have referred to this character as newline (**nl**) and

the POSIX locale character set symbolic name for the corresponding character is a <newline> character.

The command:

```
od –A o –t o2x2x –n 18
```

on a system with 32-bit words and an implementation using an input block size of 16 bytes could write 18 bytes in approximately the following format:

```
0000000 032056 031440 041123 042040 052516 044530 020043 031464
          342e   3320   4253   4420   554e   4958   2023   3334
             342e3320       42534420       554e4958       20233334
0000020 032472
          353a
             353a0000
0000022
```

The command:

```
od –A d –t f –t o4 –t x4 –n 24 –j 0x15
```

on a system with 64-bit doubles (for example, IEEE Std. 754-1985 double precision floating-point format) would skip 21 bytes of input data and then write 24 bytes in approximately the following format:

```
0000000    1.00000000000000e+00    1.57350000000000e+01
         07774000000 00000000000 10013674121 35341217270
            3ff00000    00000000    402f3851    eb851eb8
0000016    1.40668230000000e+02
         10030312542 04370303230
            40619562    23e18698
0000024
```

RATIONALE

The *od* utility went through several names in early proposals, including *hd*, *xd*, and most recently *hexdump*. There were several objections to all of these based on the following reasons:

- The *hd* and *xd* names conflicted with historical utilities that behaved differently.
- The *hexdump* description was much more complex than needed for a simple dump utility.
- The *od* utility has been available on all historical implementations and there was no need to create a new name for a utility so similar to the historical *od* utility.

The original reasons for not standardizing historical *od* were also fairly widespread. Those reasons are given below along with rationale explaining why the standard developers believe that this version does not suffer from the indicated problem:

- The BSD and System V versions of *od* have diverged, and the intersection of features provided by both does not meet the needs of the user community. In fact, the System V version only provides a mechanism for dumping octal bytes and **short**s, signed and unsigned decimal **short**s, hexadecimal **short**s, and ASCII characters. BSD added the ability to dump **float**s, **double**s, named ASCII characters, and octal, signed decimal, unsigned decimal, and hexadecimal **long**s. The version presented here provides more normalized forms for dumping bytes, **short**s, **int**s, and **long**s in octal, signed decimal, unsigned decimal, and hexadecimal; **float**, **double**, and **long double**; and named ASCII as well as current locale characters.

- It would not be possible to come up with a compatible superset of the BSD and System V flags that met the requirements of the standard developers. The historical default *od* output is the specified default output of this utility. None of the option letters chosen for this version of *od* conflict with any of the options to historical versions of *od*.

- On systems with different sizes for **short**, **int**, and **long**, there was no way to ask for dumps of **int**s, even in the BSD version. Because of the way options are named, the name space could not be extended to solve these problems. This is why the **–t** option was added (with type specifiers more closely matched to the *printf*( ) formats used in the rest of this volume of IEEE Std. 1003.1-200x) and the optional field sizes were added to the **d**, **f**, **o**, **u**, and **x** type specifiers. It is also one of the reasons why the historical practice was not mandated as a required obsolescent form of *od*. (Although the old versions of *od* are not listed as an obsolescent form, implementations are urged to continue to recognize the older forms for several more years.) The **a**, **c**, **f**, **o**, and **x** types match the meaning of the corresponding format characters in the historical implementations of *od* except for the default sizes of the fields converted. The **d** format is signed in this volume of IEEE Std. 1003.1-200x to match the *printf*( ) notation. (Historical versions of *od* used **d** as a synonym for **u** in this version. The System V implementation uses **s** for signed decimal; BSD uses **i** for signed decimal and **s** for null-terminated strings.) Other than **d** and **u**, all of the type specifiers match format characters in the historical BSD version of **od**.

  The sizes of the C-language types **char**, **short**, **int**, **long**, **float**, **double**, and **long double** are used even though it is recognized that there may be zero or more than one compiler for the C language on an implementation and that they may use different sizes for some of these types. (For example, one compiler might use 2 bytes **short**s, 2 bytes **int**s, and 4 bytes **long**s, while another compiler (or an option to the same compiler) uses 2 bytes **short**s, 4 bytes **int**s, and 4 bytes **long**s.) Nonetheless, there has to be a basic size known by the implementation for these types, corresponding to the values reported by invocations of the *getconf* utility when called with *system_var* operands {UCHAR_MAX}, {USHORT_MAX}, {UINT_MAX}, and {ULONG_MAX} for the types **char**, **short**, **int**, and **long**, respectively. There are similar constants required by the ISO C standard, but not required by the System Interfaces volume of IEEE Std. 1003.1-200x or this volume of IEEE Std. 1003.1-200x. They are {FLT_MANT_DIG}, {DBL_MANT_DIG}, and {LDBL_MANT_DIG} for the types **float**, **double**, and **long double**, respectively. If the optional *c99* utility is provided by the implementation and used as specified by this volume of IEEE Std. 1003.1-200x, these are the sizes that would be provided. If an option is used that specifies different sizes for these types, there is no guarantee that the *od* utility is able to interpret binary data output by such a program correctly.

  This volume of IEEE Std. 1003.1-200x requires that the numeric values of these lengths be recognized by the *od* utility and that symbolic forms also be recognized. Thus, a portable application can always look at an array of **unsigned long** data elements using *od* **–t** *uL*.

- The method of specifying the format for the address field based on specifying a starting offset in a file unnecessarily tied the two together. The **–A** option now specifies the address base and the **–S** option specifies a starting offset.

- It would be difficult to break the dependence on U.S. ASCII to achieve an internationalized utility. It does not seem to be any harder for *od* to dump characters in the current locale than it is for the *ed* or *sed* **l** commands. The **c** type specifier does this without difficulty and is completely compatible with the historical implementations of the **c** format character when the current locale uses a superset of the ISO / IEC 646: 1991 standard as a codeset. The **a** type specifier (from the BSD **a** format character) was left as a portable means to dump ASCII (or more correctly ISO / IEC 646: 1991 standard (IRV)) so that headers produced by *pax* could be deciphered even on systems that do not use the ISO / IEC 646: 1991 standard as a subset of

their base codeset.

The use of "***" as an indication of continuation of a multi-byte character in **c** specifier output was chosen based on seeing an implementation that uses this method. The continuation bytes have to be marked in a way that is not ambiguous with another single-byte or multi-byte character.

An early proposal used –**S** and –**n**, respectively, for the –**j** and –**N** options eventually selected. These were changed to avoid conflicts with historical implementations.

The original standard specified –**t o2** as the default when no output type was given. This was changed to –**t oS** (the length of a **short**) to accommodate a supercomputer implementation that historically used 64 bits as its default (and that defined shorts as 64 bits). This change should not affect portable applications. The requirement to support lengths of 1, 2, and 4 was added at the same time to address an historical implementation that had no two-byte data types in its C compiler.

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

FUTURE DIRECTIONS

All option and operand interfaces marked as extensions may be withdrawn in a future issue.

SEE ALSO

c99, *sed*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 4, Version 2

The description of the –**c** option is made dependent on the current setting of the *LC_CTYPE* category, and a reference to the POSIX locale is deleted.

Issue 5

In the description of the –**c** option, the phrase ‘‘This is equivalent to –**t c**.’’ is deleted.

The FUTURE DIRECTIONS section has been modified.

Issue 6

The *od* utility is changed to remove the assumption that **short** was a two-byte entity, as per the revisions in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

paste — merge corresponding or subsequent lines of files

SYNOPSIS

`paste [`–`s][`–`d` *list*`]` *file*`...`

DESCRIPTION

The *paste* utility shall concatenate the corresponding lines of the given input files, and writes the resulting lines to standard output.

The default operation of *paste* shall concatenate the corresponding lines of the input files. The <newline> character of every line except the line from the last input file shall be replaced with a <tab> character.

If an end-of-file condition is detected on one or more input files, but not all input files, *paste* shall behave as though empty lines were read from the files on which end-of-file was detected, unless the –**s** option is specified.

OPTIONS

The *paste* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–**d** *list* Unless a backslash character appears in *list*, each character in *list* is an element specifying a delimiter character. If a backslash character appears in *list*, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <tab> character, to replace the <newline> character of the input lines. The elements in *list* shall be used circularly; that is, when the list is exhausted the first element from the list is reused. When the –**s** option is specified:

- The last <newline> character in a file shall not be modified.
- The delimiter shall be reset to the first element of list after each *file* operand is processed.

When the –**s** option is not specified:

- The <newline> characters in the file specified by the last *file* operand shall not be modified.
- The delimiter shall be reset to the first element of list each time a line is processed from each file.

If a backslash character appears in *list*, it and the character following it shall be used to represent the following delimiter characters:

`\n` <newline> character.

`\t` <tab> character.

`\\` Backslash character.

`\0` Empty string (not a null character). If `'\0'` is immediately followed by the character `'x'`, the character `'X'`, or any character defined by the *LC_CTYPE* **digit** keyword (see the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 7, Locale), the results are unspecified.

If any other characters follow the backslash, the results are unspecified.

−s Concatenate all of the lines of each separate input file in command line order. The <newline> character of every line except the last line in each input file shall be replaced with the <tab> character, unless otherwise specified by the **−d** option.

OPERANDS

The following operand shall be supported:

file A path name of an input file. If '−' is specified for one or more of the *file*s, the standard input shall be used; the standard input shall be read one line at a time, circularly, for each instance of '−'. Implementations shall support pasting of at least 12 *file* operands.

STDIN

The standard input shall be used only if one or more *file* operands is '−'. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *paste*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Concatenated lines of input files shall be separated by the <tab> character (or other characters under the control of the **−d** option) and terminated by a <newline> character.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If one or more input files cannot be opened when the **–s** option is not specified, a diagnostic message shall be written to standard error, but no output is written to standard output. If the **–s** option is specified, the *paste* utility shall provide the default behavior described in Section 1.11 (on page 2224).

APPLICATION USAGE

When the escape sequences of the *list* option-argument are used in a shell script, they must be quoted; otherwise, the shell treats the `'\\'` as a special character.

Portable applications should only use the specific backslash escaped delimiters presented in this volume of IEEE Std. 1003.1-200x. Historical implementations treat `'\x'`, where `'x'` is not in this list, as `'x'`, but future implementations are free to expand this list to recognize other common escapes similar to those accepted by *printf* and other standard utilities.

Most of the standard utilities work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if *file* contains long lines:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline> character) and **file2** that contains the remainder of the data from *file*. Note that **file2** is not a text file if there are lines in *file* that are longer than 500 + {LINE_MAX} bytes. The original file can be recreated from **file1** and **file2** using the command:

```
paste –d "\0" file1 file2 > file
```

The commands:

```
paste –d "\0" ...
paste –d "" ...
```

are not necessarily equivalent; the latter is not specified by this volume of IEEE Std. 1003.1-200x and may result in an error. The construct `'\0'` is used to mean ‘‘no separator’’ because historical versions of *paste* did not follow the syntax guidelines, and the command:

```
paste –d"" ...
```

could not be handled properly by *getopt*( ).

EXAMPLES

1. Write out a directory in four columns:

   ```
   ls | paste – – – –
   ```

2. Combine pairs of lines from a file into single lines:

   ```
   paste –s –d "\t\n" file
   ```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO/IEC 9945-2:1993 standard.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

patch — apply changes to files

SYNOPSIS

UP

```
patch [–blNR][ –c| –e| –n][–d dir][–D define][–i patchfile]
    [–o outfile][–p num][–r rejectfile][file]
```

DESCRIPTION

The *patch* utility shall read a source (patch) file containing any of the three forms of difference (diff) listings produced by the *diff* utility (normal, context or in the style of *ed*) and apply those differences to a file. By default, *patch* shall read from the standard input.

The *patch* utility shall attempt to determine the type of the *diff* listing, unless overruled by a **–c**, **–e**, or **–n** option.

If the patch file contains more than one patch, *patch* shall attempt to apply each of them as if they came from separate patch files. (In this case, the application shall ensure that the name of the patch file is determinable for each *diff* listing.)

OPTIONS

The *patch* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–b Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix **.orig** appended to it. If the file already exists, it shall be overwritten; if multiple patches are applied to the same file, the **.orig** file shall be written only for the first patch. When the **–o** *outfile* option is also specified, *file***.orig** shall not be created but, if *outfile* already exists, *outfile***.orig** shall be created.

–c Interpret the patch file as a context difference (the output of the utility *diff* when the **–c** or **–C** options are specified).

–d *dir* Change the current directory to *dir* before processing as described in the EXTENDED DESCRIPTION section.

–D *define* Mark changes with one of the following C preprocessor constructs:

```
#ifdef define
...
#endif
#ifndef define
...
#endif
```

optionally combined with the C preprocessor construct **#else**.

–e Interpret the patch file as an *ed* script, rather than a *diff* script.

–i *patchfile* Read the patch information from the file named by the path name *patchfile*, rather than the standard input.

–l (The letter ell.) Cause any sequence of <blank> characters in the difference script to match any sequence of <blank> characters in the input file. Other characters shall be matched exactly.

−n Interpret the script as a normal difference.

−N Ignore patches where the differences have already been applied to the file; by default, already-applied patches shall be rejected.

−o *outfile* Instead of modifying the files (specified by the *file* operand or the difference listings) directly, write a copy of the file referenced by each patch, with the appropriate differences applied, to *outfile*. Multiple patches for a single file shall be applied to the intermediate versions of the file created by any previous patches, and shall result in multiple, concatenated versions of the file being written to *outfile*.

−p *num* For all path names in the patch file that indicate the names of files to be patched, delete *num* path name components from the beginning of each path name. If the path name in the patch file is absolute, any leading slashes shall be considered the first component (that is, **−p 1** shall remove the leading slashes). Specifying **−p 0** shall cause the full path name to be used. If **−p** is not specified, only the basename (the final path name component) shall be used.

−R Reverse the sense of the patch script; that is, assume that the difference script was created from the new version to the old version. The **−R** option cannot be used with *ed* scripts. The *patch* utility shall attempt to reverse each portion of the script before applying it. Rejected differences shall be saved in swapped format. If this option is not specified, and until a portion of the patch file is successfully applied, *patch* attempts to apply each portion in its reversed sense as well as in its normal sense. If the attempt is successful, the user shall be prompted to determine if the **−R** option should be set.

−r *rejectfile* Override the default reject file name. In the default case, the reject file shall have the same name as the output file, with the suffix **.rej** appended to it; see **Patch Application** (on page 2903).

OPERANDS

The following operand shall be supported:

file A path name of a file to patch.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *patch*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

26550 *LC_MESSAGES*
26551 Determine the locale that should be used to affect the format and contents of
26552 diagnostic messages written to standard error and informative messages written to
26553 standard output.

26554 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

26555 *LC_TIME* Determine the locale for recognizing the format of file timestamps written by the
26556 *diff* utility in a context-difference input file.

26557 **ASYNCHRONOUS EVENTS**
26558 Default.

26559 **STDOUT**
26560 Not used.

26561 **STDERR**
26562 Used for diagnostic and informational messages.

26563 **OUTPUT FILES**
26564 The output of the *patch* utility, the save files (**.orig** suffixes) and the reject files (**.rej** suffixes) shall
26565 be text files.

26566 **EXTENDED DESCRIPTION**
26567 A patchfile may contain patching instructions for more than one file; file names shall be
26568 determined as specified in **File Name Determination** (on page 2903). When the –**b** option is
26569 specified, for each patched file, the original shall be saved in a file of the same name with the
26570 suffix **.orig** appended to it.

26571 For each patched file, a reject file may also be created as noted in **Patch Application** (on page
26572 2903). In the absence of a –**r** option, the name of this file shall be formed by appending the suffix
26573 **.rej** to the original file name.

26574 **Patchfile Format**

26575 The patch file shall contain zero or more lines of header information followed by one or more
26576 patches. Each patch shall contain zero or more lines of file name identification in the format
26577 produced by *diff* –**c**, and one or more sets of *diff* output, which are customarily called *hunks*.

26578 The *patch* utility shall recognize the following expression in the header information:

26579 **Index:** *pathname*
26580 The file to be patched is named *pathname*.

26581 If all lines (including headers) within a patch begin with the same leading sequence of <blank>
26582 characters, the *patch* utility shall remove this sequence before proceeding. Within each patch, if
26583 the type of difference is context, the *patch* utility shall recognize the following expressions:

26584 *** *filename timestamp*
26585 The patches arose from *filename*.

26586 *––– filename timestamp*
26587 The patches should be applied to *filename*.

26588 Each hunk within a patch shall be the *diff* output to change a line range within the original file.
26589 The line numbers for successive hunks within a patch shall occur in ascending order.

File Name Determination

If no *file* operand is specified, *patch* shall perform the following steps to determine the file name to use:

1. If the type of *diff* is context, the *patch* utility shall delete path name components (as specified by the **–p** option) from the file name on the line beginning with "****", then test for the existence of this file relative to the current directory (or the directory specified with the **–d** option). If the file exists, the *patch* utility shall use this file name.
2. If the type of *diff* is context, the *patch* utility shall delete the path name components (as specified by the **–p** option) from the file name on the line beginning with "–––", then test for the existence of this file relative to the current directory (or the directory specified with the **–d** option). If the file exists, the *patch* utility shall use this file name.
3. If the header information contains a line beginning with the string **Index:**, the *patch* utility shall delete path name components (as specified by the **–p** option) from this line, then test for the existence of this file relative to the current directory (or the directory specified with the **–d** option). If the file exists, the *patch* utility shall use this file name.
4. XSI If an **SCCS** directory exists in the current directory, *patch* shall attempt to perform a *get* **–e SCCS/s.***filename* command to retrieve an editable version of the file. If the file exists, the *patch* utility shall use this file name.
5. The *patch* utility shall write a prompt to standard output and request a file name interactively from the controlling terminal (for example, **/dev/tty**).

Patch Application

If the **–c**, **–e**, or **–n** option is present, the *patch* utility shall interpret information within each hunk as a context difference, an *ed* difference or a normal difference, respectively. In the absence of any of these options, the *patch* utility shall determine the type of difference based on the format of information within the hunk.

For each hunk, the *patch* utility shall begin to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, *patch* shall scan both forwards and backwards at least 1 000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan shall take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context shall be ignored and another scan shall be made. Implementations may search more extensively for installation locations.

If no location can be found, the *patch* utility shall append the hunk to the reject file. The rejected hunk shall be written in context-difference format regardless of the format of the patch file. If the input was a normal or *ed–style* difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they shall reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an *ed* diff, the implementation may accomplish the patching by invoking the *ed* utility.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 One or more lines were written to a reject file.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Patches that cannot be correctly placed in the file shall be written to a reject file.

APPLICATION USAGE

The **–R** option does not work with *ed* scripts because there is too little information to reconstruct the reverse operation.

The **–p** option makes it possible to customize a patchfile to local user directory structures without manually editing the patchfile. For example, if the file name in the patch file was:

```
/curds/whey/src/blurfl/blurfl.c
```

Setting **–p 0** gives the entire path name unmodified; **–p 1** gives:

```
curds/whey/src/blurfl/blurfl.c
```

without the leading slash, **–p 4** gives:

```
blurfl/blurfl.c
```

and not specifying **–p** at all gives:

```
blurfl.c .
```

EXAMPLES

None.

RATIONALE

Some of the functionality in historical *patch* implementations was not specified. The following documents those features present in historical implementations that have not been specified.

A deleted piece of functionality was the `'+'` pseudo-option allowing an additional set of options and a patch file operand to be given. This was seen as being insufficiently useful to standardize.

In historical implementations, if the string `"Prereq:"` appeared in the header, the *patch* utility would search for the corresponding version information (the string specified in the header, delimited by <blank>s or the beginning or end of a line or the file) anywhere in the original file. This was deleted as too simplistic and insufficiently trustworthy a mechanism to standardize. For example, if:

```
Prereq: 1.2
```

were in the header, the presence of a delimited 1.2 anywhere in the file would satisfy the prerequisite.

The following options were dropped from historical implementations of *patch* as insufficiently useful to standardize:

–b The **–b** option historically provided a method for changing the name extension of the backup file from the default **.orig**. This option has been modified and retained in this volume of IEEE Std. 1003.1-200x.

–F The **–F** option specified the number of lines of a context diff to ignore when searching for a place to install a patch.

–f The **–f** option historically caused *patch* not to request additional information from the user.

–r The **–r** option historically provided a method of overriding the extension of the reject file from the default **.rej**.

–s The **–s** option historically caused *patch* to work silently unless an error occurred.

–x The **–x** option historically set internal debugging flags.

In some file system implementations, the saving of a **.orig** file may produce unwanted results. In the case of 12, 13, or 14-character file names (on file systems supporting 14-character maximum file names), the **.orig** file overwrites the new file. The reject file may also exceed this file name limit. It was suggested, due to some historical practice, that a tilde (′~′) suffix be used instead of **.orig** and some other character instead of the **.rej** suffix. This was rejected because it is not obvious to the user which file is which. The suffixes **.orig** and **.rej** are clearer and more understandable.

The **–b** option has the opposite sense in some historical implementations—do not save the **.orig** file. The default case here is not to save the files, making *patch* behave more consistently with the other standard utilities.

The **–w** option in early proposals was changed to **–l** to match historical practice.

The **–N** option was included because without it, a non-interactive application cannot reject previously applied patches. For example, if a user is piping the output of *diff* into the *patch* utility, and the user only wants to patch a file to a newer version non-interactively, the **–N** option is required.

Changes to the **–l** option description were proposed to allow matching across <newline>s in addition to just <blank>s. Since this is not historical practice, and since some ambiguities could result, it is suggested that future developments in this area utilize another option letter, such as **–L**.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The description of the **–D** option and the steps in **File Name Determination** (on page 2903) are changed to match historical practice as defined in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

pathchk — check path names

SYNOPSIS

```
pathchk [–p] pathname...
```

DESCRIPTION

The *pathchk* utility shall check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no file name truncation results). More extensive portability checks are provided by the **–p** option.

By default, the *pathchk* utility shall check each component of each *pathname* operand based on the underlying file system. A diagnostic shall be written for each *pathname* operand that:

- Is longer than {PATH_MAX} bytes (see **Path Name Variable Values** in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 13, Headers, **<limits.h>**)
- Contains any component longer than {NAME_MAX} bytes in its containing directory
- Contains any component in a directory that is not searchable
- Contains any character in any component that is not valid in its containing directory

The format of the diagnostic message is not specified, but shall indicate the error detected and the corresponding *pathname* operand.

It shall not be considered an error if one or more components of a *pathname* operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.

OPTIONS

The *pathchk* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–p Instead of performing checks based on the underlying file system, write a diagnostic for each *pathname* operand that:

- Is longer than {_POSIX_PATH_MAX} bytes (see **Minimum Values** in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 13, Headers, **<limits.h>**)
- Contains any component longer than {_POSIX_NAME_MAX} bytes
- Contains any character in any component that is not in the portable file name character set

OPERANDS

The following operand shall be supported:

pathname A path name to be checked.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pathchk*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-

26752 defined default locale shall be used. If any of the internationalization variables |
26753 contains an invalid setting, the utility shall behave as if none of the variables had
26754 been defined.

26755 *LC_ALL* If set to a non-empty string value, override the values of all the other
26756 internationalization variables.

26757 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
26758 characters (for example, single-byte as opposed to multi-byte characters in
26759 arguments).

26760 *LC_MESSAGES*
26761 Determine the locale that should be used to affect the format and contents of
26762 diagnostic messages written to standard error.

26763 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

26764 **ASYNCHRONOUS EVENTS**
26765 Default.

26766 **STDOUT**
26767 Not used.

26768 **STDERR**
26769 Used only for diagnostic messages.

26770 **OUTPUT FILES**
26771 None.

26772 **EXTENDED DESCRIPTION**
26773 None.

26774 **EXIT STATUS**
26775 The following exit values shall be returned:

26776 0 All *pathname* operands passed all of the checks.

26777 >0 An error occurred.

26778 **CONSEQUENCES OF ERRORS**
26779 Default.

26780 **APPLICATION USAGE**
26781 The *test* utility can be used to determine whether a given path name names an existing file; it
26782 does not, however, give any indication of whether or not any component of the path name was
26783 truncated in a directory where the _POSIX_NO_TRUNC feature is not in effect. The *pathchk*
26784 utility does not check for file existence; it performs checks to determine if a path name does exist
26785 or could be created with no path name component truncation.

26786 The *noclobber* option in the shell (see the *set* (on page 2297) special built-in) can be used to
26787 atomically create a file. As with all file creation semantics in the System Interfaces volume of
26788 IEEE Std. 1003.1-200x, it guarantees atomic creation, but still depends on applications to agree
26789 on conventions and cooperate on the use of files after they have been created.

26790 **EXAMPLES**
26791 To verify that all path names in an imported data interchange archive are legitimate and
26792 unambiguous on the current system:

```
26793 pax –f archive | sed –e '/ == .*/s///' | xargs pathchk
26794 if [ $? –eq 0 ]
26795 then
```

```
    pax –r –f archive
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the System Interfaces volume of IEEE Std. 1003.1-200x that also supports the *pax* utility:

```
find . –print | xargs pathchk –p
if [ $? –eq 0 ]
then
    pax –w –f archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied path name names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
case $– in
    *C*)    reset="";;
    *)      reset="set +C"
            set –C;;
esac
test –r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? –ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset    # Reset the noclobber option in case a trap
              # on EXIT depends on it.
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. **PROCESSING** represents the code that is used by the application to use **$path** once it is verified that **$path.out** works as intended.
2. The state of the *noclobber* option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The **reset** variable is used in this example to restore the initial state.)
3. Note the usage of:

   ```
   rm "$path.out" > "$path.out"
   ```

   a. The *pathchk* command has already verified, at this point, that **$path.out** is not truncated.

   b. With the *noclobber* option set, the shell verifies that **$path.out** does not already exist before invoking *rm*.

c. If the shell succeeded in creating **$path.out**, *rm* removes it so that the application can create the file again in the **PROCESSING** step.

d. If the **PROCESSING** step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:

```
> "$path.out"
```

which verifies that the file did not already exist, but leaves **$path.out** in place for use by **PROCESSING**.

RATIONALE

The *pathchk* utility is new, commissioned for this volume of IEEE Std. 1003.1-200x. It, along with the *set* **–C**(*noclobber*) option added to the shell, replaces the *mktemp*, *validfnam*, and *create* utilities that appeared in early proposals. All of these utilities were attempts to solve several common problems:

- Verify the validity (for several different definitions of ‘‘valid’’) of a path name supplied by a user, generated by an application, or imported from an external source.
- Atomically create a file.
- Perform various string handling functions to generate a temporary file name.

The *create* utility, included in an early proposal, provided checking and atomic creation in a single invocation of the utility; these are orthogonal issues and need not be grouped into a single utility. Note that the *noclobber* option also provides a way of creating a lock for process synchronization; since it provides an atomic *create*, there is no race between a test for existence and the following creation if it did not exist.

Having a function like *tmpnam*( ) in the ISO C standard is important in many high-level languages. The shell programming language, however, has built-in string manipulation facilities, making it very easy to construct temporary file names. The names needed obviously depend on the application, but are frequently of a form similar to:

$TMPDIR/***application_abbreviation***$$.*suffix*

In cases where there is likely to be contention for a given suffix, a simple shell *for* or *while* loop can be used with the shell *noclobber* option to create a file without risk of collisions, as long as applications trying to use the same file name name space are cooperating on the use of files after they have been created.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

NAME

pax — portable archive interchange

SYNOPSIS

```
pax [–cdnv][–H|–L][–f archive][–s replstr]...[pattern...]

pax –r[–cdiknuv][–H|–L][–f archive][–o options]...[–p string]...
    [–s replstr]...[pattern...]

pax –w[–dituvX][–H|–L][–b blocksize][[–a][–f archive][–o options]...
    [–s replstr]...[–x format][file...]

pax –r –w[–diklntuvX][–H|–L][–p string]...[–s replstr]...
    [file...] directory
```

DESCRIPTION

The *pax* utility shall read, write, and write lists of the members of archive files and copy directory hierarchies. A variety of archive formats shall be supported; see the **–x** *format* option.

The action to be taken depends on the presence of the **–r** and **–w** options. The four combinations of **–r** and **–w** are referred to as the four modes of operation: **list**, **read**, **write**, and **copy** modes, corresponding respectively to the four forms shown in the SYNOPSIS section.

list In **list** mode (when neither **–r** nor **–w** are specified), *pax* shall write the names of the members of the archive file read from the standard input, with path names matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file shall be listed as well.

read In **read** mode (when **–r** is specified, but **–w** is not), *pax* shall extract the members of the archive file read from the standard input, with path names matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file shall be extracted as well. The extracted files shall be created relative to the current file hierarchy.

If an attempt is made to extract a directory when the directory already exists, this shall not be considered to be an error. If an attempt is made to extract a FIFO when the FIFO already exists, this shall not be considered to be an error.

The ownership, access, and modification times, and file mode of the restored files are discussed under the **–p** option.

write In **write** mode (when **–w** is specified, but **–r** is not), *pax* shall write the contents of the *file* operands to the standard output in an archive format. If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

copy In **copy** mode (when both **–r** and **–w** are specified), *pax* shall copy the *file* operands to the destination directory.

If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

The effect of the **copy** shall be as if the copied files were written to an archive file and then subsequently extracted, except that there may be hard links between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. If the destination directory is a file of a type not defined by the System Interfaces volume of IEEE Std. 1003.1-200x,

the results are implementation-defined; otherwise, it shall be an error for the file named by the *directory* operand not to exist, not be writable by the user, or not be a file of type directory.

In **read** or **copy** modes, if intermediate directories are necessary to extract an archive member, *pax* shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x, called with the following arguments:

- The intermediate directory used as the *path* argument
- The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO as the *mode* argument

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, *pax* shall write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The archive formats described in the EXTENDED DESCRIPTION section shall be automatically detected on input. The default output archive format shall be implementation-defined.

A single archive can span multiple files. The *pax* utility shall determine, in an implementation-defined manner, what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it shall be an error if these files cannot be linked when the archive is extracted. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this *pax* session, either the data shall be restored from the original file, or a diagnostic message shall be displayed with the name of a file that can be used to extract the data. In traversing directories, *pax* shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, *pax* shall write a diagnostic message to standard error and shall terminate.

OPTIONS

The *pax* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the **−o**, **−p**, and **−s** options is significant.

The following options shall be supported:

−r Read an archive file from standard input.

−w Write files to the standard output in the specified archive format.

−a Append files to the end of the archive. It is implementation-defined which devices on the system support appending. Additional file formats unspecified by this volume of IEEE Std. 1003.1-200x may impose restrictions on appending.

−b *blocksize* Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking shall be automatically determined on input. Portable applications shall not specify a *blocksize* value larger than 32 256. Default blocking when creating archives depends on the archive format. (See the **−x** option below.)

−c Match all file or archive members except those specified by the *pattern* or *file* operands.

−d Cause files of type directory being copied or archived or archive members of type directory being extracted or listed to match only the file or archive member itself and not the file hierarchy rooted at the file.

–f *archive* Specify the path name of the input or output archive, overriding the default standard input (in **list** or **read** modes) or standard output (**write** mode).

–H If a symbolic link referencing a file of type directory is specified on the command line, *pax* shall archive the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. The default behavior shall be to archive the symbolic link itself.

–i Interactively rename files or archive members. For each archive member matching a *pattern* operand or file matching a *file* operand, a prompt shall be written to the file **/dev/tty**. The prompt shall contain the name of the file or archive member, but the format is otherwise unspecified. A line shall then be read from **/dev/tty**. If this line is blank, the file or archive member shall be skipped. If this line consists of a single period, the file or archive member shall be processed with no modification to its name. Otherwise, its name shall be replaced with the contents of the line. The *pax* utility shall immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if **/dev/tty** cannot be opened for reading and writing.

The results of extracting a hard link to a file that has been renamed during extraction are unspecified.

–k Prevent the overwriting of existing files.

–l (The letter ell.) In **copy** mode, hard links shall be made between the source and destination file hierarchies whenever possible.

–L If a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *pax* shall archive the file hierarchy rooted in the file referenced by the link, using the name of the link as the root of the file hierarchy. The default behavior shall be to archive the symbolic link itself.

–n Select the first archive member that matches each *pattern* operand. No more than one archive member shall be matched for each pattern (although members of type directory shall still match the file hierarchy rooted at that file).

–o *options* Provide information to the implementation to modify the algorithm for extracting or writing files. The value of *options* shall consist of one or more comma-separated keywords of the form:

keyword[[:]=*value*][,*keyword*[[:]=*value*], ...]

Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.

Keywords in the *options* argument shall be a string that would be a valid portable file name as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.282, Portable File Name Character Set.

Note: Keywords are not expected to be file names, merely to follow the same character composition rules as portable file names.

Keywords can be preceded with white space. The *value* field shall consist of zero or more characters; within *value*, the application shall precede any literal comma with a backslash, which shall be ignored, but preserves the comma as part of *value*. A comma as the final character, or a comma followed solely by white space as the final characters, in *options* shall be ignored. Multiple **–o** options can be specified; if

keywords given to these multiple –**o** options conflict, the keywords and values appearing later in command line sequence shall take precedence and the earlier shall be silently ignored. The following keyword values of *options* shall be supported for the file formats as indicated:

delete=*pattern*
(Applicable only to the –**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall omit from extended header records that it produces any keywords matching the string pattern. When used in **read** or **list** mode, *pax* shall ignore any keywords matching the string pattern in the extended header records. In both cases, matching shall be performed using the pattern matching notation described in Section 2.14.1 (on page 2274) and Section 2.14.2 (on page 2274). For example:

```
–o delete=security.*
```

would suppress security-related information. See **pax Extended Header** (on page 2923) for extended header record keyword usage.

exthdr.name=*string*
(Applicable only to the –**x** *pax* format.) This keyword allows user control over the name that is written into the **ustar** header blocks for the extended header produced under the circumstances described in **pax Header Block** (on page 2922). The name shall be the contents of *string*, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
%d	The directory name of the file, equivalent to the result of the *dirname* utility on the translated path name.
%f	The file name of the file, equivalent to the result of the *basename* utility on the translated path name.
%%	A '%' character.

Any other '%' characters in *string* produce undefined results.

If no –**o exthdr.name=***string* is specified, *pax* shall use the following default value:

```
%d/PaxHeaders/%f
```

globexthdr.name=*string*
(Applicable only to the –**x** *pax* format.) When used in **write** or **copy** mode with the appropriate options, *pax* creates global extended header records with **ustar** header blocks that will be treated as regular files by previous versions of *pax*. This keyword allows user control over the name that is written into the **ustar** header blocks for global extended header records. The name shall be the contents of string, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
%n	An integer that represents the sequence number of the global extended header record in the archive, starting at 1.
%%	A '%' character.

27059 Any other '%' characters in *string* produce undefined results.

27060 If no –**o globexthdr.name=***string* is specified, *pax* shall use the following
27061 default value:

27062 `$TMPDIR/GlobalHead.%n`

27063 where $*TMPDIR* represents the value of the *TMPDIR* environment variable. If
27064 *TMPDIR* is not set, *pax* shall use **/tmp**.

27065 **invalid**=*action*
27066 (Applicable only to the –**x** *pax* format.) This keyword allows user control over
27067 the action *pax* takes upon encountering values in an extended header record
27068 that, in **read** or **copy** mode, are invalid in the destination hierarchy or, in **list**
27069 mode, cannot be written in the codeset and current locale of the
27070 implementation. The following are invalid values that shall be recognized by
27071 *pax*:

27072 — In **read** or **copy** mode, a file name or link name that contains character
27073 encodings invalid in the destination hierarchy. (For example, the name
27074 may contain embedded NULs.)

27075 — In **read** or **copy** mode, a file name or link name that is longer than the
27076 maximum allowed in the destination hierarchy (for either a path name
27077 component or the entire path name).

27078 — In **list** mode, any character string value (file name, link name, user name,
27079 and so on) that cannot be written in the codeset and current locale of the
27080 implementation.

27081 The following mutually-exclusive values of the *action* argument are
27082 supported:

27083 **bypass** In **read** or **copy** mode, *pax* shall bypass the file, causing no
27084 change to the destination hierarchy. In **list** mode, *pax* shall write
27085 all requested valid values for the file, but its method for writing
27086 invalid values is unspecified.

27087 **rename** In **read** or **copy** mode, *pax* shall act as if the –**i** option were in
27088 effect for each file with invalid file name or link name values,
27089 allowing the user to provide a replacement name interactively.
27090 In **list** mode, *pax* shall behave identically to the **bypass** action.

27091 **UTF-8** When used in **read**, **copy**, or **list** mode and a file name, link
27092 name, owner name, or any other field in an extended header
27093 record cannot be translated from the *pax* UTF-8 codeset format
27094 to the codeset and current locale of the implementation, *pax*
27095 shall use the actual UTF-8 encoding for the name.

27096 **write** In **read** or **copy** mode, *pax* shall write the file, translating or
27097 truncating the name, regardless of whether this may overwrite
27098 an existing file with a valid name. In **list** mode, *pax* shall behave
27099 identically to the **bypass** action.

27100 If no –**o invalid=** option is specified, *pax* shall act as if –**oinvalid=bypass** were
27101 specified. Any overwriting of existing files that may be allowed by the
27102 –**oinvalid=** actions shall be subject to permission (–**p**) and modification time
27103 (–**u**) restrictions, and shall be suppressed if the –**k** option is also specified.

linkdata (Applicable only to the –**x** *pax* format.) In **write** mode, *pax* shall write the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

listopt=*format*
This keyword specifies the output format of the table of contents produced when the –**v** option is specified in **list** mode. See **List Mode Format Specifications** (on page 2918). To avoid ambiguity, the **listopt=***format* shall be the only or final **keyword=***value* pair in a –**o** option-argument; all characters in the remainder of the option-argument shall be considered part of the format string. When multiple –**olistopt=***format* options are specified, the format strings shall be considered a single, concatenated string, evaluated in command line order.

times
(Applicable only to the –**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall include **atime**, **ctime**, and **mtime** extended header records for each file. See **pax Extended Header File Times** (on page 2926).

In addition to these keywords, if the –**x** *pax* format is specified, any of the keywords and values defined in **pax Extended Header** (on page 2923), including implementation extensions, can be used in –**o** option-arguments, in either of two modes:

keyword=*value*
When used in **write** or **copy** mode, these keyword/value pairs shall be included at the beginning of the archive as **typeflag g** global extended header records. When used in **read** or **list** mode, these keyword/value pairs shall act as if they had been at the beginning of the archive as **typeflag g** global extended header records.

keyword:=*value*
When used in **write** or **copy** mode, these keyword/value pairs shall be included as records at the beginning of a **typeflag x** extended header for each file. (This is equivalent to the equal-sign form except that it creates no **typeflag g** global extended header records.) When used in **read** or **list** mode, these keyword/value pairs shall act as if they were included as records at the end of each extended header; thus, they shall override any global or file-specific extended header record keywords of the same names. For example, in the command:

```
pax –r –o "
gname:=mygroup,
" <archive
```

the group name will be forced to a new value for all files read from the archive.

The precedences of –**o** keywords over various fields in the archive are described in **pax Extended Header Keyword Precedence** (on page 2925).

–**p** *string* Specify one or more file characteristic options (privileges). The *string* option-argument shall be a string specifying file characteristics to be retained or discarded on extraction. The string shall consist of the specification characters **a**, **e**, **m**, **o**, and **p**. Other implementation-defined characters can be included. Multiple characteristics can be concatenated within the same string and multiple –**p** options can be specified. The meaning of the specification characters are as follows:

a Do not preserve file access times.

e Preserve the user ID, group ID, file mode bits (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.170, File Mode Bits), access time, modification time, and any other implementation-defined file characteristics.

m Do not preserve file modification times.

o Preserve the user ID and group ID.

p Preserve the file mode bits. Other implementation-defined file mode attributes may be preserved.

In the preceding list, ''preserve'' indicates that an attribute stored in the archive shall be given to the extracted file, subject to the permissions of the invoking process. The access and modification times of the file shall be preserved unless otherwise specified with the –**p** option or not stored in the archive. All attributes that are not preserved shall be determined as part of the normal file creation action (see Section 1.7.1.4 (on page 2209)).

If neither the **e** nor the **o** specification character is specified, or the user ID and group ID are not preserved for any reason, *pax* shall not set the S_ISUID and S_ISGID bits of the file mode.

If the preservation of any of these items fails for any reason, *pax* shall write a diagnostic message to standard error. Failure to preserve these items shall affect the final exit status, but shall not cause the extracted file to be deleted.

If file characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last shall take precedence. For example, if –**p eme** is specified, file modification times are preserved.

–**s** *replstr* Modify file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, using the syntax of the *ed* utility. The concepts of ''address'' and ''line'' are meaningless in the context of the *pax* utility, and shall not be supplied. The format shall be:

–s */old/new/*[gp]

where as in *ed*, *old* is a basic regular expression and *new* can contain an ampersand, '\n' (where *n* is a digit) backreferences, or subexpression matching. The *old* string also shall be permitted to contain <newline> characters.

Any non-null character can be used as a delimiter ('/' shown here). Multiple –**s** expressions can be specified; the expressions shall be applied in the order specified, terminating with the first successful substitution. The optional trailing 'g' is as defined in the *ed* utility. The optional trailing 'p' shall cause successful substitutions to be written to standard error. File or archive member names that substitute to the empty string shall be ignored when reading and writing archives.

–**t** Cause the access times of the archived files to be the same as they were before being read by *pax*.

–**u** Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name. In **read** mode, an archive member with the same name as a file in the file system shall be extracted if the archive member is newer than the file. In **write** mode, an archive file member with the same name as a file in the file system shall be superseded if the file is newer than the archive member. If –**a** is also specified, this is accomplished by appending

to the archive; otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive. In **copy** mode, the file in the destination hierarchy shall be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

–v In **list** mode, produce a verbose table of contents (see the STDOUT section). Otherwise, write archive member path names to standard error (see the STDERR section).

–x *format* Specify the output archive format. The *pax* utility shall support the following formats:

cpio The *cpio* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

pax The *pax* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

ustar The *tar* interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 10 240. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

Implementation-defined formats shall specify a default block size as well as any other block sizes supported for character special archive files.

Any attempt to append to an archive file in a format different from the existing archive format shall cause *pax* to exit immediately with a non-zero exit status.

In **copy** mode, if no **–x** format is specified, *pax* shall behave as if **–x***pax* were specified.

–X When traversing the file hierarchy specified by a path name, *pax* shall not descend into directories that have a different device ID (*st_dev*; see the System Interfaces volume of IEEE Std. 1003.1-200x, *stat*( )).

The options that operate on the names of files or archive members (**–c**, **–i**, **–n**, **–s**, **–u**, and **–v**) shall interact as follows. In **read** mode, the archive members shall be selected based on the user-specified *pattern* operands as modified by the **–c**, **–n**, and **–u** options. Then, any **–s** and **–i** options shall modify, in that order, the names of the selected files. The **–v** option shall write names resulting from these modifications.

In **write** mode, the files shall be selected based on the user-specified path names as modified by the **–n** and **–u** options. Then, any **–s** and **–i** options shall modify, in that order, the names of these selected files. The **–v** option shall write names resulting from these modifications.

If both the **–u** and **–n** options are specified, *pax* shall not consider a file selected unless it is newer than the file to which it is compared.

27237 **List Mode Format Specifications**

27238 In **list** mode with the –**o listopt=***format* option, the *format* argument shall be applied for each
27239 selected file. The *pax* utility shall append a <newline> character to the **listopt** output for each
27240 selected file. The format argument shall be used as the *format* string described in the Base
27241 Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation, with the
27242 exceptions 1. through 5. defined in the EXTENDED DESCRIPTION section of *printf*, plus the
27243 following exceptions:

27244 6. The sequence (*keyword*) can occur before a format conversion specifier. The conversion
27245 argument is defined by the value of *keyword*. The implementation shall support the
27246 following keywords:

27247 — Any of the Field Name entries in Table 4-13 (on page 2927) and Table 4-15 (on page
27248 2930). The implementation may support the *cpio* keywords without the leading **c_** in
27249 addition to the form required by Table 4-16 (on page 2931).

27250 — Any keyword defined for the extended header in **pax Extended Header** (on page 2923).

27251 — Any keyword provided as an implementation-defined extension within the extended
27252 header defined in **pax Extended Header** (on page 2923).

27253 For example, the sequence `"%(charset)s"` is the string value of the name of the character
27254 set in the extended header.

27255 The result of the keyword conversion argument shall be the value from the applicable
27256 header field or extended header, without any trailing NULs.

27257 All keyword values used as conversion arguments shall be translated from the UTF-8
27258 encoding to the character set appropriate for the local file system, user database, and so on,
27259 as applicable.

27260 7. An additional conversion character, **T**, shall be used to specify time formats. The **T**
27261 conversion character can be preceded by the sequence (*keyword=subformat*), where *subformat*
27262 is a date format as defined by *date* operands. The default *keyword* shall be **mtime** and the
27263 default subformat shall be:

27264 `%b %e %H:%M %Y`

27265 8. An additional conversion character, **M**, shall be used to specify the file mode string as
27266 defined in *ls* Standard Output. If (*keyword*) is omitted, the **mode** keyword shall be used. For
27267 example, **%.1M** writes the single character corresponding to the <*entry type*> field of the *ls*
27268 **–l** command.

27269 9. An additional conversion character, **D**, shall be used to specify the device for block or
27270 special files, if applicable, in an implementation-defined format. If not applicable, and
27271 (*keyword*) is specified, then this conversion shall be equivalent to **%**(*keyword*)**u**. If not
27272 applicable, and (*keyword*) is omitted, then this conversion shall be equivalent to <space>.

27273 10. An additional conversion character, **F**, shall be used to specify a path name. The **F**
27274 conversion character can be preceded by a sequence of comma-separated keywords:

27275 `(`*keyword*`[,`*keyword*`] ... )`

27276 The values for all the keywords that are non-null shall be concatenated together, each
27277 separated by a `'/'`. The default shall be (**path**) if the keyword **path** is defined; otherwise,
27278 the default shall be (**prefix**,**name**).

27279 11. An additional conversion character, **L**, shall be used to specify a symbolic line expansion. If
27280 the current file is a symbolic link, then **%L** shall expand to:

27281 `"%s -> %s", <value of keyword>, <contents of link>`

27282 Otherwise, the **%L** conversion character shall be the equivalent of **%F**.

27283 **OPERANDS**

27284 The following operands shall be supported:

27285 *directory* The destination directory path name for **copy** mode.

27286 *file* A path name of a file to be copied or archived.

27287 *pattern* A pattern matching one or more path names of archive members. A pattern must
27288 be given in the name-generating notation of the pattern matching notation in
27289 Section 2.14 (on page 2274), including the file name expansion rules in Section
27290 2.14.3 (on page 2275). The default, if no *pattern* is specified, is to select all members
27291 in the archive.

27292 **STDIN**

27293 In **write** mode, the standard input shall be used only if no *file* operands are specified. It shall be a
27294 text file containing a list of path names, one per line, without leading or trailing <blank>
27295 characters.

27296 In **list** and **read** modes, if **–f** is not specified, the standard input shall be an archive file.

27297 Otherwise, the standard input shall not be used.

27298 **INPUT FILES**

27299 The input file named by the *archive* option-argument, or standard input when the archive is read
27300 from there, shall be a file formatted according to one of the specifications in the EXTENDED |
27301 DESCRIPTION section or some other implementation-defined format. |

27302 The file **/dev/tty** shall be used to write prompts and read responses.

27303 **ENVIRONMENT VARIABLES**

27304 The following environment variables shall affect the execution of *pax*:

27305 *LANG* Provide a default value for the internationalization variables that are unset or null.
27306 If *LANG* is unset or null, the corresponding value from the implementation- |
27307 defined default locale shall be used. If any of the internationalization variables |
27308 contains an invalid setting, the utility shall behave as if none of the variables had
27309 been defined.

27310 *LC_ALL* If set to a non-empty string value, override the values of all the other
27311 internationalization variables.

27312 *LC_COLLATE*
27313 Determine the locale for the behavior of ranges, equivalence classes and multi-
27314 character collating elements used in the pattern matching expressions for the
27315 *pattern* operand, the basic regular expression for the **–s** option, and the extended
27316 regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES*
27317 category.

27318 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
27319 characters (for example, single-byte as opposed to multi-byte characters in
27320 arguments and input files), the behavior of character classes used in the extended
27321 regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES*
27322 category, and pattern matching.

27323 *LC_MESSAGES*
27324 Determine the locale for the processing of affirmative responses that should be

used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings when the **–v** option is specified.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the path name that provides part of the default global extended header record file, as described for the **–o globexthdr=** keyword as described in the OPTIONS section.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In **write** mode, if **–f** is not specified, the standard output shall be the archive formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format (see **–x** *format*).

In **list** mode, when the **–olistopt**=*format* has been specified, the selected archive members shall be written to standard output using the format described under **List Mode Format Specifications** (on page 2918). In **list** mode without the **–olistopt**=*format* option, the table of contents of the the selected archive members shall be written to standard output using the following format:

`"%s\n", <`*path name*`>`

If the **–v** option is specified in **list** mode, the table of contents of the selected archive members shall be written to standard output using the following formats.

For path names representing hard links to previous members of the archive:

`"%sΔ==Δ%s\n", <`*ls* `–l` *listing*`>, <`*linkname*`>`

For all other path names:

`"%s\n", <`*ls* `–l` *listing*`>`

where <*ls* –l *listing*> shall be the format specified by the *ls* utility with the **–l** option. When writing path names in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of <blank> character-separated fields shall be written.

In **list** mode, standard output shall not be buffered more than a line at a time.

STDERR

If **–v** is specified in **read**, **write**, or **copy** modes, *pax* shall write the path names it processes to the standard error output using the following format:

`"%s\n", <`*path name*`>`

These path names shall be written as soon as processing is begun on the file or archive member, and shall be flushed to standard error. The trailing <newline> character, which shall not be buffered, is written when the file has been read or written.

If the **–s** option is specified, and the replacement string has a trailing `'p'`, substitutions shall be written to standard error in the following format:

`"%sΔ>>Δ%s\n", <`*original path name*`>, <`*new path name*`>`

In all operating modes of *pax*, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in path names or link names are written.

When *pax* is in **read** mode or **list** mode, using the **–xpax** archive format, and a file name, link name, owner name, or any other field in an extended header record cannot be translated from the *pax* UTF-8 codeset format to the codeset and current locale of the implementation, *pax* shall write a diagnostic message to standard error, shall process the file as described for the **–o invalid=**option, and then shall process the next file in the archive.

OUTPUT FILES

In **read** mode, the extracted output files shall be of the archived file type. In **copy** mode, the copied output files shall be the type of the file being copied. In either mode, existing files in the destination hierarchy shall be overwritten only when all permission (**–p**), modification time (**–u**), and invalid-value (**–oinvalid**=) tests allow it.

In **write** mode, the output file named by the **–f** option-argument shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format.

EXTENDED DESCRIPTION

pax Interchange Format

A *pax* archive tape or file produced in the **–x***pax* format shall contain a series of blocks. The physical layout of the archive shall be identical to the **ustar** format described in **ustar Interchange Format** (on page 2926). Each file archived shall be represented by the following sequence:

- An optional header block with extended header records. This header block is of the form described in **pax Header Block** (on page 2922), with a *typeflag* value of **x** or **g**. The extended header records, described in **pax Extended Header** (on page 2923), are included as the data for this header block.
- A header block that describes the file. Any fields in the preceding optional extended header override the associated fields in this header block for this file.
- Zero or more blocks that contain the contents of the file.

At the end of the archive file there shall be two 512-byte blocks filled with binary zeroes, interpreted as an end-of-archive indicator.

A schematic of an example archive with global extended header records and two actual files is shown in Figure 4-1 (on page 2922). In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.

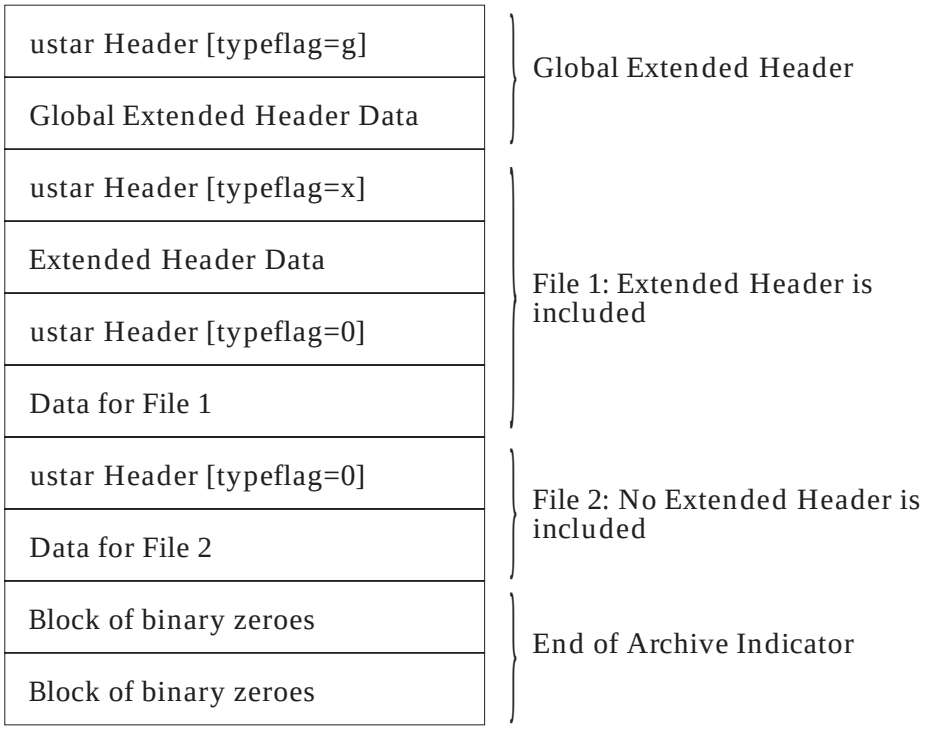

Figure 4-1 pax Format Archive Example

pax Header Block

The *pax* header block shall be identical to the **ustar** header block described in **ustar Interchange Format** (on page 2926), except that two additional *typeflag* values are defined:

x Represents extended header records for the following file in the archive (which shall have its own **ustar** header block). The format of these extended header records shall be as described in **pax Extended Header** (on page 2923).

g Represents global extended header records for the following files in the archive. The format of these extended header records shall be as described in **pax Extended Header** (on page 2923). Each value shall affect all subsequent files that do not override that value in their own extended header record and until another global extended header record is reached that provides another value for the same field. The *typeflag* **g** global headers should not be used with interchange media that could suffer partial data loss in transporting the archive.

For both of these types, the *size* field shall be the size of the extended header records in octets. The other fields in the header block are not meaningful to this version of the *pax* utility. However, if this archive is read by a *pax* utility conforming to a previous version of IEEE Std. 1003.1-200x, the header block fields are used to create a regular file that contains the extended header records as data. Therefore, header block field values should be selected to provide reasonable file access to this regular file.

A further difference from the **ustar** header block is that data blocks for files of *typeflag* 1 (the digit one) (hard link) may be included, which means that the size field may be greater than zero. Archives created by **pax –o linkdata** shall include these data blocks with the hard links.

pax Extended Header

A *pax* extended header contains values that are inappropriate for the **ustar** header block because of limitations in that format: fields requiring a character encoding other than that described in the ISO/IEC 646:1991 standard, fields representing file attributes not described in the **ustar** header, and fields whose format or length do not fit the requirements of the **ustar** header. The values in an extended header add attributes to the following file (or files; see the description of the *typeflag* **g** header block) or override values in the following header block(s), as indicated in the following list of keywords.

An extended header shall consist of one or more records, each constructed as follows:

"%d %s=%s\n", <*length*>, <*keyword*>, <*value*>

The extended header records shall be encoded according to the ISO/IEC 10646-1:1993 standard (UTF-8). The <*length*> field, <blank> character, equals sign, and <newline> character shown shall be limited to the portable character set, as encoded in UTF-8. The <*keyword*> and <*value*> fields can be any UTF-8 characters. The <*length*> field shall be the decimal length of the extended header record in octets, including the trailing <newline> character.

The <*keyword*> field shall be one of the entries from the following list or a keyword provided as an implementation extension. Keywords consisting entirely of lowercase letters, digits, and periods are reserved for future standardization. A keyword shall not include an equals sign. (In the following list, the notations ''file(s)'' or ''block(s)'' is used to acknowledge that a keyword affects the following single file after a *typeflag* **x** extended header, but possibly multiple files after *typeflag* **g**. Any requirements in the list for *pax* to include a record when in **write** or **copy** mode shall apply only when such a record has not already been provided through the use of the **−o** option. When used in **copy** mode, *pax* shall behave as if an archive had been created with applicable extended header records and then extracted.)

atime The file access time for the following file(s), equivalent to the value of the *st_atime* member of the **stat** structure for a file, as described by the *stat*( ) function. The access time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2926).

charset The name of the character set used to encode the data in the following file(s). The entries in the following table are defined to refer to known standards; additional names may be agreed on between the originator and recipient.

<value>	Formal Standard
ISO-IR∆646∆1990	ISO/IEC 646:1990
ISO-IR∆8859∆1∆1987	ISO/IEC 8859-1:1987
ISO-IR∆8859∆2∆1987	ISO/IEC 8859-2:1987
ISO-IR∆10646∆1993	ISO/IEC 10646:1993
ISO-IR∆10646∆1993∆UTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None.

The encoding is included in an extended header for information only; when *pax* is used as described in IEEE Std. 1003.1-200x, it shall not translate the file data into any other encoding. The **BINARY** entry indicates unencoded binary data.

When used in **write** or **copy** mode, it is implementation-defined whether *pax* includes a **charset** extended header record for a file.

comment A series of characters used as a comment. All characters in the <*value*> field shall be ignored by *pax*.

ctime The file creation time for the following file(s), equivalent to the value of the *st_ctime* member of the **stat** structure for a file, as described by the *stat*( ) function. The creation time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2926).

gid The group ID of the group that owns the file, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *gid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *gid* extended header record for each file whose group ID is greater than 2 097 151 (octal 7 777 777).

gname The group of the file(s), formatted as a group name in the group database. This record shall override the *gid* and *gname* fields in the following header block(s), and any *gid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the UTF-8 encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the **−oinvalid=**UTF-8 option is not specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **gname** extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.

linkpath The path name of a link being created to another file, of any type, previously archived. This record shall override the *linkname* field in the following **ustar** header block(s). The following **ustar** header block shall determine the type of link created. If *typeflag* of the following header block is 1, it shall be a hard link. If *typeflag* is 2, it shall be a symbolic link and the **linkpath** value shall be the contents of the symbolic link. The *pax* utility shall translate the name of the link (contents of the symbolic link) from the UTF-8 encoding to the character set appropriate for the local file system. When used in **write** or **copy** mode, *pax* shall include a **linkpath** extended header record for each link whose path name cannot be represented entirely with the members of the portable character set other than NUL.

mtime The file modification time of the following file(s), equivalent to the value of the *st_mtime* member of the **stat** structure for a file, as described in the *stat*( ) function. This record shall override the *mtime* field in the following header block(s). The modification time shall be restored if the process has the appropriate privilege required to do so. The format of the <*value*> shall be as described in **pax Extended Header File Times** (on page 2926).

path The path name of the following file(s). This record shall override the *name* and *prefix* fields in the following header block(s). The *pax* utility shall translate the path name of the file from the UTF-8 encoding to the character set appropriate for the local file system.

When used in **write** or **copy** mode, *pax* shall include a *path* extended header record for each file whose path name cannot be represented entirely with the members of the portable character set other than NUL.

realtime.*any* The keywords prefixed by ‘‘realtime.’’ are reserved for future standardization.

security.*any* The keywords prefixed by ‘‘security.’’ are reserved for future standardization.

size The size of the file in octets, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *size* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a

size extended header record for each file with a size value greater than 8 589 934 591 (octal 7 777 777 777).

uid The user ID of the file owner, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *uid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *uid* extended header record for each file whose owner ID is greater than 2 097 151 (octal 7 777 777).

uname The owner of the following file(s), formatted as a user name in the user database. This record shall override the *uid* and *uname* fields in the following header block(s), and any *uid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the UTF-8 encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the UTF-8 characters cannot be translated, and if the **–oinvalid=** UTF-8 option is not specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **uname** extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set.

If the <*value*> field is zero length, it shall delete any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in a **–o** option-argument) overrides or deletes a corresponding field in the **ustar** header block, *pax* shall ignore the contents of that header block field.

Unlike the **ustar** header block fields, NULs shall not delimit <*value*>s; all characters within the <*value*> field shall be considered data for the field. None of the length limitations of the **ustar** header block fields in Table 4-13 (on page 2927) shall apply to the extended header records.

pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When *pax* is used in **read** or **list** modes, it shall determine a file attribute in the following sequence:

1. If **–odelete=***keyword-prefix* is used, the affected attributes shall be determined from step 7., if applicable, or ignored otherwise.
2. If **–o***keyword*:= is used, the affected attributes shall be ignored.
3. If **–o***keyword***:=***value* is used, the affected attribute shall be assigned the value.
4. If there is a *typeflag* **x** extended header record, the affected attribute shall be assigned the <*value*>. When extended header records conflict, the last one given in the header shall take precedence.
5. If **–o***keyword***=***value* is used, the affected attribute shall be assigned the value.
6. If there is a *typeflag* **g** global extended header record, the affected attribute shall be assigned the <*value*>. When global extended header records conflict, the last one given in the global header shall take precedence.
7. Otherwise, the attribute shall be determined from the **ustar** header block.

pax Extended Header File Times

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 158 proposes new wording for the first half of the following paragraph: "pax shall write an mtime record for each file in write or copy modes if the file's modification time cannot be represented exactly in the ustar header block described in ustar Interchange Format. This can occur if the time is out of ustar range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer."

The *pax* utility shall write **atime** and **ctime** records for each file in **write** or **copy** modes only if the –**otimes** option is specified; *pax* shall write a **mtime** record for each file in **write** or **copy** modes if the file system of the underlying implementation supports time granularities smaller than that required by the **ustar** header block described in **ustar Interchange Format**. All of these time records shall be formatted as a decimal representation of the time in seconds since the Epoch. If a period (`'.'`) decimal point character is present, the digits to the right of the point shall represent the units of a subsecond timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. Implementations may ignore any portion of the subsecond digits for which they do not support the necessary timing granularity; they shall not perform any rounding operation.

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

D3, XCU, ERN 173, proposes new text for the previous sentence because a pax implementation on a single platform should not be allowed to lose information when it writes an extended header time and then reads it back in again: "In read or copy mode, the pax utility shall truncate the time of a file to the greatest value that is not greater than the input header file time. In write or copy mode, the pax utility shall output a time exactly if it can be represented exactly as a decimal number, and otherwise shall generate only enough digits so that the same time shall be recovered if the file is extracted on a system whose underlying implementation supports the same time granularity."

ustar Interchange Format

A **ustar** archive tape or file shall contain a series of blocks. Each block shall be a fixed-size block of 512 octets (see below). Although this format may be thought of as being stored on 9-track industry-standard 12.7mm (0.5in) magnetic tape, other types of transportable media are not excluded. Each file archived shall be represented by a header block that describes the file, followed by zero or more blocks that give the contents of the file. At the end of the archive file there shall be two 512-octet blocks filled with binary zeros, interpreted as an end-of-archive indicator.

The blocks may be grouped for physical I/O operations, as described under the –**b***blocksize* and –**x ustar** options. Each group of blocks may be written with a single operation equivalent to the *write*( ) function. On magnetic tape, the result of this write shall be a single tape record. The last group of blocks always shall be at the full size, so blocks after the two zero blocks may contain undefined data.

The header block shall be structured as shown in the following table. All lengths and offsets are in decimal.

Table 4-13 ustar Header Block

Field Name	Octet Offset	Length (in Octets)
name	0	100
mode	100	8
uid	108	8
gid	116	8
size	124	12
mtime	136	12
chksum	148	8
typeflag	156	1
linkname	157	100
magic	257	6
version	263	2
uname	265	32
gname	297	32
devmajor	329	8
devminor	337	8
prefix	345	155

All characters in the header block shall be represented in the coded character set of the ISO/IEC 646:1991 standard. For maximum portability between implementations, names should be selected from characters represented by the portable file name character set as octets with the most significant bit zero. If an implementation supports the use of characters outside of slash and the portable file name character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes.

However, the *pax* utility shall never create file names on the local system that cannot be accessed via the procedures described in IEEE Std. 1003.1-200x. If a file name is found on the medium that would create an invalid file name, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. The *pax* utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

Each field within the header block is contiguous; that is, there is no padding used. Each character on the archive medium shall be stored contiguously.

The fields *magic*, *uname*, and *gname* are character strings each terminated by a NUL character. The fields *name*, *linkname*, and *prefix* are NUL-terminated character strings except when all characters in the array contain non-NUL characters including the last character. The *version* field is two octets containing the characters `"00"` (zero-zero). The *typeflag* contains a single character. All other fields are leading zero-filled octal numbers using digits from the ISO/IEC 646:1991 standard IRV. Each numeric field is terminated by one or more <space> or NUL characters.

The *name* and the *prefix* fields shall produce the path name of the file. A new path name shall be formed, if *prefix* is not an empty string (its first character is not NUL), by concatenating *prefix* (up to the first NUL character), a slash character, and *name*; otherwise, *name* is used alone. In either case, *name* is terminated at the first NUL character. If *prefix* begins with a NUL character, it shall be ignored. In this manner, path names of at most 256 characters can be supported. If a path name does not fit in the space provided, *pax* shall notify the user of the error, and shall not store any part of the file—header or data—on the medium.

The *linkname* field, described below, shall not use the *prefix* to produce a path name. As such, a *linkname* is limited to 100 characters. If the name does not fit in the space provided, *pax* shall notify the user of the error, and shall not attempt to store the link on the medium.

The *mode* field provides 12 bits encoded in the ISO/IEC 646:1991 standard octal digit representation. The encoded bits shall represent the following values:

Table 4-14 ustar *mode* Field

Bit Value	IEEE Std. 1003.1-200x Bit	Description
04 000	S_ISUID	Set UID on execution.
02 000	S_ISGID	Set GID on execution.
01 000	<reserved>	Reserved for future standardization.
00 400	S_IRUSR	Read permission for file owner class.
00 200	S_IWUSR	Write permission for file owner class.
00 100	S_IXUSR	Execute/search permission for file owner class.
00 040	S_IRGRP	Read permission for file group class.
00 020	S_IWGRP	Write permission for file group class.
00 010	S_IXGRP	Execute/search permission for file group class.
00 004	S_IROTH	Read permission for file other class.
00 002	S_IWOTH	Write permission for file other class.
00 001	S_IXOTH	Execute/search permission for file other class.

When appropriate privilege is required to set one of these mode bits, and the user restoring the files from the archive does not have the appropriate privilege, the mode bits for which the user does not have appropriate privilege shall be ignored. Some of the mode bits in the archive format are not mentioned elsewhere in this volume of IEEE Std. 1003.1-200x. If the implementation does not support those bits, they may be ignored.

The *uid* and *gid* fields are the user and group ID of the owner and group of the file, respectively.

The *size* field is the size of the file in octets. If the *typeflag* field is set to specify a file to be of type 1 (a link) or 2 (reserved for symbolic links), the *size* field shall be specified as zero. If the *typeflag* field is set to specify a file of type 5 (directory), the *size* field shall be interpreted as described under the definition of that record type. No data blocks are stored for types 1, 2, or 5. If the *typeflag* field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the *size* field is unspecified by this volume of IEEE Std. 1003.1-200x, and no data blocks shall be stored on the medium. Additionally, for type 6, the *size* field shall be ignored when reading. If the *typeflag* field is set to any other value, the number of blocks written following the header shall be (*size*+511)/512, ignoring any fraction in the result of the division.

The *mtime* field shall be the modification time of the file at the time it was archived. It is the ISO/IEC 646:1991 standard representation of the octal value of the modification time obtained from the *stat*( ) function.

The *chksum* field shall be the ISO/IEC 646:1991 standard IRV representation of the octal value of the simple sum of all octets in the header block. Each octet in the header shall be treated as an unsigned value. These values shall be added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the *chksum* field is treated as if it were all spaces.

The *typeflag* field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privilege to create that type, the file shall be extracted as if it were a regular file if the file type is defined to have a meaning for the *size* field that could cause data blocks to be written on the medium (see the previous description for *size*). If conversion to a regular file occurs, the *pax* utility shall produce an error indicating that the conversion took place. All of the *typeflag* fields shall be coded in the ISO/IEC 646:1991 standard IRV:

`0` Represents a regular file. For backward compatibility, a *typeflag* value of binary zero (`'\0'`) should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a *typeflag* value of the ISO/IEC 646:1991 standard IRV `'0'`.

`1` Represents a file linked to another file, of any type, previously archived. Such files are identified by each file having the same device and file serial number. The linked-to name is specified in the *linkname* field with a NUL-character terminator if it is less than 100 octets in length.

`2` Represents a symbolic link. The contents of the symbolic link shall be stored in the *linkname* field.

`3,4` Represent character special files and block special files respectively. In this case the *devmajor* and *devminor* fields shall contain information defining the device, the format of which is unspecified by this volume of IEEE Std. 1003.1-200x. Implementations may map the device specifications to their own local specification or may ignore the entry.

`5` Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the *size* field shall contain the maximum number of octets (which may be rounded to the nearest disk block allocation unit) that the directory may hold. A *size* field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the *size* field.

`6` Specifies a FIFO special file. Note that the archiving of a FIFO file archives the existence of this file and not its contents.

`7` Reserved to represent a file to which an implementation has associated some high-performance attribute. Implementations without such extensions should treat this file as a regular file (type 0).

`A-Z` The letters `'A'` to `'Z'`, inclusive, are reserved for custom implementations. All other values are reserved for future revisions of IEEE Std. 1003.1-200x.

The *magic* field is the specification that this archive was output in this archive format. If this field contains **ustar** (the five characters from the ISO/IEC 646:1991 standard IRV shown followed by NUL), the *uname* and *gname* fields shall contain the ISO/IEC 646:1991 standard IRV representation of the owner and group of the file, respectively (truncated to fit, if necessary). When the file is restored by a privileged, protection-preserving version of the utility, the user and group databases shall be scanned for these names. If found, the user and group IDs contained within these files shall be used rather than the values contained within the *uid* and *gid* fields.

cpio Interchange Format

The octet-oriented *cpio* archive format shall be a series of entries, each comprising a header that describes the file, the name of the file, and then the contents of the file.

An archive may be recorded as a series of fixed-size blocks of octets. This blocking shall be used only to make physical I/O more efficient. The last group of blocks shall be always at the full size.

For the octet-oriented *cpio* archive format, the individual entry information shall be in the order indicated and described by the following table; see also the **<cpio.h>** header.

27740 **Table 4-15** Octet-Oriented *cpio* Archive Entry

27741 **Header Field Name**	**Length (in Octets)**	**Interpreted as**
27742 *c_magic*	6	Octal number
27743 *c_dev*	6	Octal number
27744 *c_ino*	6	Octal number
27745 *c_mode*	6	Octal number
27746 *c_uid*	6	Octal number
27747 *c_gid*	6	Octal number
27748 *c_nlink*	6	Octal number
27749 *c_rdev*	6	Octal number
27750 *c_mtime*	11	Octal number
27751 *c_namesize*	6	Octal number
27752 *c_filesize*	11	Octal number
27753 **File Name Field Name**	**Length**	**Interpreted as**
27754 *c_name*	*c_namesize*	Path name string
27755 **File Data Field Name**	**Length**	**Interpreted as**
27756 *c_filedata*	*c_filesize*	Data

27757 **cpio Header**

27758 For each file in the archive, a header as defined previously shall be written. The information in
27759 the header fields is written as streams of the ISO/IEC 646:1991 standard characters interpreted
27760 as octal numbers. The octal numbers shall be extended to the necessary length by appending the
27761 ISO/IEC 646:1991 standard IRV zeros at the most-significant-digit end of the number; the result
27762 is written to the most-significant digit of the stream of octets first. The fields shall be interpreted
27763 as follows:

27764 *c_magic* Identify the archive as being a transportable archive by containing the identifying
27765 value `"070707"`.

27766 *c_dev*, *c_ino* Contains values that uniquely identify the file within the archive (that is, no files
27767 contain the same pair of *c_dev* and *c_ino* values unless they are links to the same
27768 file). The values shall be determined in an unspecified manner.

27769 *c_mode* Contains the file type and access permissions as defined in the following table.

Table 4-16 Values for *cpio c_mode* Field

File Permissions Name	Value	Indicates
C_IRUSR	000 400	Read by owner
C_IWUSR	000 200	Write by owner
C_IXUSR	000 100	Execute by owner
C_IRGRP	000 040	Read by group
C_IWGRP	000 020	Write by group
C_IXGRP	000 010	Execute by group
C_IROTH	000 004	Read by others
C_IWOTH	000 002	Write by others
C_IXOTH	000 001	Execute by others
C_ISUID	004 000	Set *uid*
C_ISGID	002 000	Set *gid*
C_ISVTX	001 000	Reserved
File Type Name	**Value**	**Indicates**
C_ISDIR	040 000	Directory
C_ISFIFO	010 000	FIFO
C_ISREG	0100 000	Regular file
C_ISBLK	060 000	Block special file
C_ISCHR	020 000	Character special file
C_ISCTG	0110 000	Reserved
C_ISLNK	0120 000	Reserved
C_ISSOCK	0140 000	Reserved

Directories, FIFOs, and regular files shall be supported on a system conforming to this volume of IEEE Std. 1003.1-200x; additional values defined previously are reserved for compatibility with existing systems. Additional file types may be supported; however, such files should not be written to archives intended to be transported to other systems.

c_uid Contains the user ID of the owner.

c_gid Contains the group ID of the group.

c_nlink Contains the number of links referencing the file at the time the archive was created.

c_rdev Contains implementation-defined information for character or block special files.

c_mtime Contains the latest time of modification of the file at the time the archive was created.

c_namesize Contains the length of the path name, including the terminating NUL character.

c_filesize Contains the length of the file in octets. This shall be the length of the data section following the header structure.

27808 **cpio File Name**

27809 The *c_name* field shall contain the path name of the file. The length of this field in octets is the
27810 value of *c_namesize*.

27811 MAN If a file name is found on the medium that would create an invalid path name, it is
27812 implementation-defined whether the data from the file is stored on the file hierarchy and under
27813 what name it is stored.

27814 All characters shall be represented in the ISO/IEC 646:1991 standard IRV. For maximum
27815 portability between implementations, names should be selected from characters represented by
27816 the portable file name character set as octets with the most significant bit zero. If an
27817 implementation supports the use of characters outside the portable file name character set in
27818 names for files, users, and groups, one or more implementation-defined encodings of these
27819 characters shall be provided for interchange purposes. However, the *pax* utility shall never
27820 create file names on the local system that cannot be accessed via the procedures described
27821 previously in this volume of IEEE Std. 1003.1-200x. If a file name is found on the medium that
27822 would create an invalid file name, it is implementation-defined whether the data from the file is
27823 stored on the local file system and under what name it is stored. The *pax* utility may choose to
27824 ignore these files as long as it produces an error indicating that the file is being ignored.

27825 **cpio File Data**

27826 Following *c_name*, there shall be *c_filesize* octets of data. Interpretation of such data occurs in a
27827 manner dependent on the file. If *c_filesize* is zero, no data shall be contained in *c_filedata*.

27828 MAN When restoring from an archive:

27829 • If the user does not have the appropriate privilege to create a file of the specified type, *pax*
27830 shall ignore the entry and write an error message to standard error.

27831 • Only regular files have data to be restored. Presuming a regular file meets any selection
27832 criteria that might be imposed on the format-reading utility by the user, such data shall be
27833 restored.

27834 • If a user does not have appropriate privilege to set a particular mode flag, the flag shall be
27835 ignored. Some of the mode flags in the archive format are not mentioned elsewhere in this
27836 volume of IEEE Std. 1003.1-200x. If the implementation does not support those flags, they
27837 may be ignored.

27838

27839 **cpio Special Entries**

27840 FIFO special files, directories, and the trailer shall be recorded with *c_filesize* equal to zero. For
27841 other special files, *c_filesize* is unspecified by this volume of IEEE Std. 1003.1-200x. The header
27842 for the next file entry in the archive shall be written directly after the last octet of the file entry
27843 preceding it. A header denoting the file name **TRAILER!!!** indicates the end of the archive; the
27844 contents of octets in the last block of the archive following such a header are undefined.

27845 **EXIT STATUS**

27846 The following exit values shall be returned:

27847 0 All files were processed successfully.

27848 >0 An error occurred.

CONSEQUENCES OF ERRORS

If *pax* cannot create a file or a link when reading an archive or cannot find a file when writing an archive, or cannot preserve the user ID, group ID, or file mode when the **−p** option is specified, a diagnostic message shall be written to standard error and a non-zero exit status shall be returned, but processing shall continue. In the case where *pax* cannot create a link to a file, *pax* shall not, by default, create a second copy of the file.

If the extraction of a file from an archive is prematurely terminated by a signal or error, *pax* may have only partially extracted the file or (if the **−n** option was not specified) may have extracted a file of the same name as that specified by the user, but which is not the file the user wanted. Additionally, the file modes of extracted directories may have additional bits from the S_IRWXU mask set as well as incorrect modification and access times.

APPLICATION USAGE

The **−p** (privileges) option was invented to reconcile differences between historical *tar* and *cpio* implementations. In particular, the two utilities use **−m** in diametrically opposed ways. The **−p** option also provides a consistent means of extending the ways in which future file attributes can be addressed, such as for enhanced security systems or high-performance files. Although it may seem complex, there are really two modes that are most commonly used:

−p e ‘‘Preserve everything’’. This would be used by the historical superuser, someone with all the appropriate privileges, to preserve all aspects of the files as they are recorded in the archive. The **e** flag is the sum of **o** and **p**, and other implementation-defined attributes.

−p p ‘‘Preserve’’ the file mode bits. This would be used by the user with regular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.

The one path name per line format of standard input precludes path names containing <newline> characters. Although such path names violate the portable file name guidelines, they may exist and their presence may inhibit usage of *pax* within shell scripts. This problem is inherited from historical archive programs. The problem can be avoided by listing file name arguments on the command line instead of on standard input.

It is almost certain that appropriate privileges are required for *pax* to accomplish parts of this volume of IEEE Std. 1003.1-200x. Specifically, creating files of type block special or character special, restoring file access times unless the files are owned by the user (the **−t** option), or preserving file owner, group, and mode (the **−p** option) all probably require appropriate privileges.

In **read** mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This may fail if permissions on the first version of the file do not permit it to be overwritten.

The **cpio** and **ustar** formats can only support files up to 8 gigabytes in size.

EXAMPLES

The following command:

```
pax −w −f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures. The historical BSD device name would be **/dev/rmt9**).

The following commands:

```
mkdir newdir
pax –rw olddir newdir
```

copy the *olddir* directory hierarchy to *newdir*.

```
pax –r –s ',^//*usr//*,,' –f a.pax
```

reads the archive **a.pax**, with all files rooted in **/usr** in the archive extracted relative to the current directory.

Using the option:

```
–o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
–rw–rw––– Jan 12 15:53 1492 /usr/foo/bar
```

Using the options:

```
–o listopt='%L\t%(size)D\n%.7' \
–o listopt='(name)s\n%(ctime)T\n%T'
```

overrides the default output description in Standard Output and instead writes:

```
/usr/foo/bar –> /tmp   1492
/usr/fo
Jan 12 1991
Jan 31 15:53
```

RATIONALE

The *pax* utility was new, commissioned for the ISO POSIX-2:1993 standard. It represents a peaceful compromise between advocates of the historical *tar* and *cpio* utilities.

A fundamental difference between *cpio* and *tar* was in the way directories were treated. The *cpio* utility did not treat directories differently from other files, and to select a directory and its contents required that each file in the hierarchy be explicitly specified. For *tar*, a directory matched every file in the file hierarchy it rooted.

The *pax* utility offers both interfaces; by default, directories map into the file hierarchy they root. The **–d** option causes *pax* to skip any file not explicitly referenced, as *cpio* historically did. The *tar –style* behavior was chosen as the default because it was believed that this was the more common usage and because *tar* is the more commonly available interface, as it was historically provided on both System V and BSD implementations.

The data interchange format specification in this volume of IEEE Std. 1003.1-200x requires that processes with ''appropriate privileges'' shall always restore the ownership and permissions of extracted files exactly as archived. If viewed from the historic equivalence between superuser and ''appropriate privileges'', there are two problems with this requirement. First, users running as superusers may unknowingly set dangerous permissions on extracted files. Second, it is needlessly limiting, in that superusers cannot extract files and own them as superuser unless the archive was created by the superuser. (It should be noted that restoration of ownerships and permissions for the superuser, by default, is historical practice in *cpio*, but not in *tar*.) In order to avoid these two problems, the *pax* specification has an additional ''privilege'' mechanism, the **–p** option. Only a *pax* invocation with the privileges needed, and which has the **–p** option set using the **e** specification character, has the ''appropriate privilege'' to restore full ownership and permission information.

Note also that this volume of IEEE Std. 1003.1-200x requires that the file ownership and access permissions shall be set, on extraction, in the same fashion as the *creat*( ) function when provided

the mode stored in the archive. This means that the file creation mask of the user is applied to the file permissions.

Users should note that directories may be created by *pax* while extracting files with permissions that are different from those that existed at the time the archive was created. When extracting sensitive information into a directory hierarchy that no longer exists, users are encouraged to set their file creation mask appropriately to protect these files during extraction.

The table of contents output is written to standard output to facilitate pipeline processing.

An early proposal had hard links displaying for all path names. This was removed because it complicates the output of the case where **–v** is not specified and does not match historical *cpio* usage. The hard-link information is available in the **–v** display.

The archive formats inherited from the POSIX.1-1990 standard have certain restrictions that have been brought along from historical usage. For example, there are restrictions on the length of path names stored in the archive. When *pax* is used in **copy**(**–rw**) mode (copying directory hierarchies), the ability to use extensions from the **–x***pax* format overcomes these restrictions.

The default *blocksize* value of 5 120 bytes for *cpio* was selected because it is one of the standard block-size values for *cpio*, set when the **–B** option is specified. (The other default block-size value for *cpio* is 512 bytes, and this was considered to be too small.) The default block value of 10 240 bytes for *tar* was selected because that is the standard block-size value for BSD *tar*. The maximum block size of 32 256 bytes (2^{15}–512 bytes) is the largest multiple of 512 bytes that fits into a signed 16-bit tape controller transfer register. There are known limitations in some historical systems that would prevent larger blocks from being accepted. Historical values were chosen to improve compatibility with historical scripts using *dd* or similar utilities to manipulate archives. Also, default block sizes for any file type other than character special file has been deleted from this volume of IEEE Std. 1003.1-200x as unimportant and not likely to affect the structure of the resulting archive.

Implementations are permitted to modify the block-size value based on the archive format or the device to which the archive is being written. This is to provide implementations with the opportunity to take advantage of special types of devices, and it should not be used without a great deal of consideration as it almost certainly decreases archive portability.

The intended use of the **–n** option was to permit extraction of one or more files from the archive without processing the entire archive. This was viewed by the standard developers as offering significant performance advantages over historical implementations. The **–n** option in early proposals had three effects; the first was to cause special characters in patterns to not be treated specially. The second was to cause only the first file that matched a pattern to be extracted. The third was to cause *pax* to write a diagnostic message to standard error when no file was found matching a specified pattern. Only the second behavior is retained by this volume of IEEE Std. 1003.1-200x, for many reasons. First, it is in general not acceptable for a single option to have multiple effects. Second, the ability to make pattern matching characters act as normal characters is useful for parts of *pax* other than file extraction. Third, a finer degree of control over the special characters is useful because users may wish to normalize only a single special character in a single file name. Fourth, given a more general escape mechanism, the previous behavior of the **–n** option can be easily obtained using the **–s** option or a *sed* script. Finally, writing a diagnostic message when a pattern specified by the user is unmatched by any file is useful behavior in all cases.

In this version, the **–n** was removed from the **copy** mode synopsis of *pax*; it is inapplicable because there are no pattern operands specified in this mode.

There is another method than *pax* for copying subtrees in IEEE Std. 1003.1-200x described as part of the *cp* utility. Both methods are historical practice: *cp* provides a simpler, more intuitive

interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

A single archive may span more than one file. It is suggested that implementations provide informative messages to the user on standard error whenever the archive file is changed.

The **–d** option (do not create intermediate directories not listed in the archive) found in early proposals was originally provided as a complement to the historic **–d** option of *cpio*. It has been deleted.

The **–s** option in early proposals specified a subset of the substitution command from the *ed* utility. As there was no reason for only a subset to be supported, the **–s** option is now compatible with the current *ed* specification. Since the delimiter can be any non-null character, the following usage with single spaces is valid:

```
pax –s " foo bar " ...
```

The **–t** option (specify an implementation-defined identifier naming an input or output device) found in early proposals has been deleted because it is not historical practice and is of limited utility. In particular, historic versions of neither *cpio* nor *tar* had the concept of devices that were not mapped into the file system; if the devices are mapped into the file system, the **–f** option is sufficient.

The default behavior of *pax* with regard to file modification times is the same as historical implementations of *tar*. It is not the historical behavior of *cpio*.

Because the **–i** option uses **/dev/tty**, utilities without a controlling terminal are not able to use this option.

The **–y** option, found in early proposals, has been deleted because a line containing a single period for the **–i** option has equivalent functionality. The special lines for the **–i** option (a single period and the empty line) are historical practice in *cpio*.

In early drafts, an **–e***charmap* option was included to increase portability of files between systems using different coded character sets. This option was omitted because it was apparent that consensus could not be formed for it. In this version, the use of UTF-8 should be an adequate substitute.

The **–k** option was added to address international concerns about the dangers involved in the character set transformations of **–e** (if the target character set were different than the source, the file names might be transformed into names matching existing files) and also was made more general to protect files transferred between file systems with different {NAME_MAX} values (truncating a file name on a smaller system might also inadvertently overwrite existing files). As stated, it prevents any overwriting, even if the target file is older than the source. This version adds more granularity of options to solve this problem by introducing the **–oinvalid=** option—specifically the UTF-8 action. (Note that an existing file that is named with a UTF-8 encoding is still subject to overwriting in this case. The **–k** option closes that loophole.)

Some of the file characteristics referenced in this volume of IEEE Std. 1003.1-200x might not be supported by some archive formats. For example, neither the *tar* nor *cpio* formats contain the file access time. For this reason, the **e** specification character has been provided, intended to cause all file characteristics specified in the archive to be retained.

It is required that extracted directories, by default, have their access and modification times and permissions set to the values specified in the archive. This has obvious problems in that the directories are almost certainly modified after being extracted and that directory permissions may not permit file creation. One possible solution is to create directories with the mode specified in the archive, as modified by the *umask* of the user, with sufficient permissions to allow file creation. After all files have been extracted, *pax* would then reset the access and modification times and permissions as necessary.

The list-mode formatting description borrows heavily from the one defined by the *printf* utility. However, since there is no separate operand list to get conversion arguments, the format was extended to allow specifying the name of the conversion argument as part of the conversion specification.

The **T** specifier allows time fields to be displayed in any of the date formats. Unlike the *ls* utility, *pax* does not adjust the format when the date is less than six months in the past. This makes parsing the output more predictable.

The **D** specifier handles the ability to display the major/minor or file size, as with *ls*, by using **%–8(size)D**.

The **L** specifier handles the *ls* display for symbolic links.

Conversion specifiers were added to generate existing known types used for *ls*.

pax Interchange Format

The new POSIX data interchange format was developed primarily to satisfy international concerns that the **ustar** and *cpio* formats did not provide for file, user, and group names encoded in characters outside a subset of the ISO/IEC 646:1991 standard. The standard developers realized that this new POSIX data interchange format should be very extensible because there were other requirements they foresaw in the near future:

- Support international character encodings and locale information
- Support security information (ACLs, and so on)
- Support future file types, such as realtime or contiguous files
- Include data areas for implementation use
- Support systems with words larger than 32 bits and timers with subsecond granularity

The following were not goals for this format because these are better handled by separate utilities or are inappropriate for a portable format:

- Encryption
- Compression
- Data translation between locales and codesets
- *inode* storage

The format chosen to support the goals is an extension of the **ustar** format. Of the two formats previously available, only the **ustar** format was selected for extensions because:

- It was easier to extend in an upward-compatible way. It offered version flags and header block type fields with room for future standardization. The *cpio* format, while possessing a more flexible file naming methodology, could not be extended without breaking some theoretical implementation or using a dummy file name that could be a legitimate file name.

- Industry experience since the original ‘‘tar wars’’ fought in developing the ISO POSIX-1 standard has clearly been in favor of the **ustar** format, which is generally the default output format selected for *pax* implementations on new systems.

The new format was designed with one additional goal in mind: reasonable behavior when an older *tar* or *pax* utility happened to read an archive. Since the POSIX.1-1990 standard mandated that a ‘‘format-reading utility’’ had to treat unrecognized *typeflag* values as regular files, this allowed the format to include all the extended information in a pseudo-regular file that preceded each real file. An option is given that allows the archive creator to set up reasonable names for these files on the older systems. Also, the normative text suggests that reasonable file access values be used for this **ustar** header block. Making these header files inaccessible for convenient reading and deleting would not be reasonable. File permissions of 600 or 700 are suggested.

The **ustar** *typeflag* field was used to accommodate the additional functionality of the new format rather than magic or version because the POSIX.1-1990 standard (and, by reference, the previous version of *pax*), mandated the behavior of the format-reading utility when it encountered an unknown *typeflag*, but was silent about the other two fields.

Early proposals of the first revision to IEEE Std. 1003.1-200x contained a proposed archive format that was based on compatibility with the standard for tape files (ISO 1001, similar to the format used historically on many mainframes and minicomputers). This format was overly complex and required considerable overhead in volume and header records. Furthermore, the standard developers felt that it would not be acceptable to the community of POSIX developers, so it was later changed to be a format more closely related to historical practice on POSIX systems.

The prefix and name split of path names in **ustar** was replaced by the single path extended header record for simplicity.

The concept of a global extended header (*typeflag* **g**) was controversial. If this were applied to an archive being recorded on magnetic tape, a few unreadable blocks at the beginning of the tape could be a serious problem; a utility attempting to extract as many files as possible from a damaged archive could lose a large percentage of file header information in this case. However, if the archive were on a reliable medium, such as a CD-ROM, the global extended header offers considerable potential size reductions by eliminating redundant information. Thus, the text warns against using the global method for unreliable media and provides a method for implanting global information in the extended header for each file, rather than in the *typeflag* **g** records.

No facility for data translation or filtering on a per-file basis is included because the standard developers could not invent an interface that would allow this in an efficient manner. If a filter, such as encryption or compression, is to be applied to all the files, it is more efficient to apply the filter to the entire archive as a single file. The standard developers considered interfaces that would invoke a shell script for each file going into or out of the archive, but the system overhead in this approach was considered to be too high.

One such approach would be to have **filter=** records that give a path name for an executable. When the program is invoked, the file and archive would be open for standard input/output and all the header fields would be available as environment variables or command-line arguments. The standard developers did discuss such schemes, but they were omitted from IEEE Std. 1003.1-200x due to concerns about excessive overhead. Also, the program itself would need to be in the archive if it were to be used portably.

There is currently no portable means of identifying the character set(s) used for a file in the file system. Therefore, *pax* has not been given a mechanism to generate charset records automatically. The only portable means of doing this is for the user to write the archive using the

28120 –**ocharset=***string* command line option. This assumes that all of the files in the archive use the
28121 same encoding. The ‘‘implementation-defined’’ text is included to allow for a system that can
28122 identify the encodings used for each of its files.

28123 The table of standards that accompanies the charset record description is acknowledged to be
28124 very limited. Only a limited number of character set standards is reasonable for maximal
28125 interchange. Any character set is, of course, possible by prior agreement. It was suggested that
28126 EBCDIC be listed, but it was omitted because it is not defined by a formal standard. Formal
28127 standards, and then only those with reasonably large followings, can be included here, simply as
28128 a matter of practicality. The <*value*>s represent names of officially registered charactersets in the
28129 format required by the ISO 2375: 1985 standard.

28130 The normal comma or <blank>-separated list rules are not followed in the case of keyword
28131 options to allow ease of argument parsing for *getopts*.

28132 Further information on character encodings is in **pax Archive Character Set Encoding/Decoding**
28133 (on page 2941).

28134 The standard developers have reserved keyword name space for vendor extensions. It is
28135 suggested that the format to be used is:

28136 `VENDOR.keyword`

28137 where *VENDOR* is the name of the vendor or organization in all uppercase letters. It is further
28138 suggested that the keyword following the period be named differently than any of the standard
28139 keywords so that it could be used for future standardization, if appropriate, by omitting the
28140 *VENDOR* prefix.

28141 The <*length*> field in the extended header record was included to make it simpler to step
28142 through the records, even if a record contains an unknown format (to a particular *pax*) with
28143 complex interactions of special characters. It also provides a minor integrity checkpoint within
28144 the records to aid a program attempting to recover files from a damaged archive.

28145 There are no extended header versions of the *devmajor* and *devminor* fields because the
28146 unspecified format **ustar** header field should be sufficient. If they are not, vendor-specific
28147 extended keywords (such as *VENDOR.devmajor*) should be used.

28148 Device and *i*-number labeling of files was not adopted from *cpio*; files are interchanged strictly
28149 on a symbolic name basis, as in **ustar**.

28150 Just as with the **ustar** format descriptions, the new format makes no special arrangements for
28151 multi-volume archives. Each of the *pax* archive types is assumed to be inside a single POSIX file
28152 and splitting that file over multiple volumes (diskettes, tape cartridges, and so on), processing
28153 their labels, and mounting each in the proper sequence are considered to be implementation
28154 details that cannot be described portably.

28155 The *pax* format is intended for interchange, not only for backup on a single (family of) systems. It
28156 is not as densely packed as might be possible for backup:

28157 - It contains information as coded characters that could be coded in binary.
28158 - It identifies extended records with name fields that could be omitted in favor of a fixed-field
28159 layout.
28160 - It translates names into a portable character set and identifies locale-related information,
28161 both of which are probably unnecessary for backup.

28162 The requirements on restoring from an archive are slightly different from the historical wording,
28163 allowing for non-monolithic privilege to bring forward as much as possible. In particular,
28164 attributes such as ‘‘high performance file’’ might be broadly but not universally granted while

28165 set-user-ID or *chown*() might be much more restricted. There is no implication in
28166 IEEE Std. 1003.1-200x that the security information be honored after it is restored to the file
28167 hierarchy, in spite of what might be improperly inferred by the silence on that topic. That is a
28168 topic for another standard.

28169 Links are recorded in the fashion described here because a link can be to any file type. It is
28170 desirable in general to be able to restore part of an archive selectively and restore all of those
28171 files completely. If the data is not associated with each link, it is not possible to do this.
28172 However, the data associated with a file can be large, and when selective restoration is not
28173 needed, this can be a significant burden. The archive is structured so that files that have no
28174 associated data can always be restored by the name of any link name of any link, and the user
28175 may choose whether data is recorded with each instance of a file that contains data. The format
28176 permits mixing of both types of links in a single archive; this can be done for special needs, and
28177 *pax* is expected to interpret such archives on input properly, despite the fact that there is no *pax*
28178 option that would force this mixed case on output. (When **−o linkdata** is used, the output must
28179 contain the duplicate data, but the implementation is free to include it or omit it when **−o**
28180 **linkdata** is not used.)

28181 The time values are included as extended header records for those implementations needing
28182 more than the eleven octal digits allowed by the **ustar** format. Portable file timestamps cannot be
28183 negative. If *pax* encounters a file with a negative timestamp in **copy** or **write** mode, it can reject
28184 the file, substitute a non-negative timestamp, or generate a non-portable timestamp with a
28185 leading '-'. Even though some implementations can support finer file-time granularities than
28186 seconds, the normative text requires support only for seconds since the Epoch because the
28187 ISO POSIX-1 standard states them that way. The **ustar** format includes only *mtime*; the new
28188 format adds *atime* and *ctime* for symmetry. The *atime* access time restored to the file system will
28189 be affected by the **−p a** and **−p e** options. The *ctime* creation time (actually *inode* modification
28190 time) is described with ''appropriate privilege'' so that it can be ignored when writing to the file
28191 system. POSIX does not provide a portable means to change file creation time. Nothing is
28192 intended to prevent a non-portable implementation of *pax* from restoring the value.

28193 The *gid*, *size*, and *uid* extended header records were included to allow expansion beyond the
28194 sizes specified in the regular *tar* header. New file system architectures are emerging that will
28195 exhaust the 12-digit size field. There are probably not many systems requiring more than 8 digits
28196 for user and group IDs, but the extended header values were included for completeness,
28197 allowing overrides for all of the decimal values in the *tar* header.

28198 The standard developers intended to describe the effective results of *pax* with regard to file
28199 ownerships and permissions; implementations are not restricted in timing or sequencing the
28200 restoration of such, provided the results are as specified.

28201 Much of the text describing the extended headers refers to use in ''**write** or **copy** modes''. The
28202 **copy** mode references are due to the normative text: ''The effect of the copy shall be as if the
28203 copied files were written to an archive file and then subsequently extracted ...''. There is
28204 certainly no way to test whether *pax* is actually generating the extended headers in **copy** mode,
28205 but the effects must be as if it had.

pax Archive Character Set Encoding/Decoding

There is a need to exchange archives of files between systems of different native codesets. File names, group names, and user names must be preserved to the fullest extent possible when an archive is read on the receiving platform. Translation of the contents of files is not within the scope of the *pax* utility.

There will also be the need to represent glyphs that are not available on the receiving platform. (A *glyph* is commonly called a character, but without any reference to a specific encoding of that character. The term *glyph* refers to the symbol itself.) These unsupported glyphs cannot be automatically folded to the local set of glyphs due to the chance of collisions. This could result in overwriting previous extracted files from the archive or pre-existing files on the system.

For these reasons, the codeset used to represent glyphs within the extended header records of the *pax* archive must be sufficiently rich to handle all commonly used character sets. The fields requiring translation include, at a minimum, file names, user names, group names, and link path names. Implementations may wish to have localized extended keywords that use non-portable characters.

The standard developers considered the following options:

- The archive creator specifies the well-defined name of the source codeset. The receiver must then recognize the codeset name and perform the appropriate translations to the destination codeset.
- The archive creator includes within the archive the character mapping table for the source codeset used to encode extended header records. The receiver must then read the character mapping table and perform the appropriate translations to the destination codeset.
- The archive creator translates the extended header records in the source codeset into a canonical form. The receiver must then perform the appropriate translations to the destination codeset.

The approach that incorporates the name of the source codeset poses the problem of codeset name registration, and makes the archive useless to *pax* archive decoders that do not recognize that codeset.

Because parts of an archive may be corrupted, the standard developers felt that including the character map of the source codeset was too fragile. The loss of this one key component could result in making the entire archive useless. (The difference between this and the global extended header decision was that the latter has a workaround—duplicating extended header records on unreliable media—but this would be too burdensome for large character set maps.)

Both of the above approaches also put an undue burden on the *pax* archive receiver to handle the cross-product of all source and destination codesets.

To simplify the translation from the source codeset to the canonical form and from the canonical form to the destination codeset, the standard developers decided that the internal representation should be a stateless encoding. A stateless encoding is one where each codepoint has the same meaning, without regard to the decoder being in a specific state. An example of a stateful encoding would be the Japanese Shift-JIS; an example of a stateless encoding would be the ISO/IEC 646:1991 standard (equivalent to 7-bit ASCII).

For these reasons, the standard developers decided to adopt a canonical format for the representation of file information strings. The obvious, well-endorsed candidate is the ISO/IEC 10646-1:1993 standard (based in part on Unicode), which can be used to represent the glyphs of virtually all standardized character sets. The standard developers initially agreed upon using UCS2 (16-bit Unicode) as the internal representation. This repertoire of glyphs provides a

sufficiently rich set to represent all commonly-used codesets.

However, the standard developers found that the 16-bit Unicode representation had some problems. It forced the issue of standardizing byte ordering. The 2-byte length of each character made the extended header records twice as long for the case of strings coded entirely from historical 7-bit ASCII. For these reasons, the standard developers chose the UTF-8 defined in the ISO/IEC 10646-1:1993 standard. This multi-byte representation encodes UCS2 or UCS4 characters reliably and deterministically, eliminating the need for a canonical byte ordering. In addition, NUL octets and other characters possibly confusing to POSIX file systems do not appear, except to represent themselves. It was realized that certain national codesets take up more space after the encoding, due to their placement within the UCS range; it was felt that the usefulness of the encoding of the names outweighs the disadvantage of size increase for file, user, and group names.

The encoding of UTF-8 is as follows:

```
UCS4 Hex Encoding  UTF-8 Binary Encoding

00000000-0000007F  0xxxxxxx
00000080-000007FF  110xxxxx 10xxxxxx
00000800-0000FFFF  1110xxxx 10xxxxxx 10xxxxxx
00010000-001FFFFF  11110xxx 10xxxxxx 10xxxxxx 10xxxxxx
00200000-03FFFFFF  111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
04000000-7FFFFFFF  1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

where each 'x' represents a bit value from the character being translated.

ustar Interchange Format

The description of the **ustar** format reflects numerous enhancements over pre-1988 versions of the historical *tar* utility. The goal of these changes was not only to provide the functional enhancements desired, but also to retain compatibility between new and old versions. This compatibility has been retained. Archives written using the old archive format are compatible with the new format.

Implementors should be aware that the previous file format did not include a mechanism to archive directory type files. For this reason, the convention of using a file name ending with slash was adopted to specify a directory on the archive.

The total size of the *name* and *prefix* fields have been set to meet the minimum requirements for {PATH_MAX}. If a path name will fit within the *name* field, it is recommended that the path name be stored there without the use of the *prefix* field. Although the name field is known to be too small to contain {PATH_MAX} characters, the value was not changed in this version of the archive file format to retain backward compatibility, and instead the prefix was introduced. Also, because of the earlier version of the format, there is no way to remove the restriction on the *linkname* field being limited in size to just that of the *name* field.

The *size* field is required to be meaningful in all implementation extensions, although it could be zero. This is required so that the data blocks can always be properly counted.

It is suggested that if device special files need to be represented that cannot be represented in the standard format that one of the extension types (**A**-**Z**) be used, and that the additional information for the special file be represented as data and be reflected in the *size* field.

Attempting to restore a special file type, where it is converted to ordinary data and conflicts with an existing file name, need not be specially detected by the utility. If run as an ordinary user, *pax* should not be able to overwrite the entries in, for example, **/dev** in any case (whether the file is converted to another type or not). If run as a privileged user, it should be able to do so,

and it would be considered a bug if it did not. The same is true of ordinary data files and similarly named special files; it is impossible to anticipate the needs of the user (who could really intend to overwrite the file), so the behavior should be predictable (and thus regular) and rely on the protection system as required.

The value 7 in the *typeflag* field is intended to define how contiguous files can be stored in a **ustar** archive. IEEE Std. 1003.1-200x does not require the contiguous file extension, but does define a standard way of archiving such files so that all conforming systems can interpret these file types in a meaningful and consistent manner. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

The file protection modes are those conventionally used by the *ls* utility. This is extended beyond the usage in the ISO POSIX-2 standard to support the ''shared text'' or ''sticky'' bit. It is intended that the conformance document should not document anything beyond the existence of and support of such a mode. Further extensions are expected to these bits, particularly with overloading the set-user-ID and set-group-ID flags.

cpio Interchange Format

The reference to appropriate privilege in the *cpio* format refers to an error on standard output; the **ustar** format does not make comparable statements.

The model for this format was the historical System V *cpio*–**c** data interchange format. This model documents the portable version of the *cpio* format and not the binary version. It has the flexibility to transfer data of any type described within IEEE Std. 1003.1-200x, yet is extensible to transfer data types specific to extensions beyond IEEE Std. 1003.1-200x (for example, contiguous files). Because it describes existing practice, there is no question of maintaining upward compatibility.

cpio Header

There has been some concern that the size of the *c_ino* field of the header is too small to handle those systems that have very large *inode* numbers. However, the *c_ino* field in the header is used strictly as a hard-link resolution mechanism for archives. It is not necessarily the same value as the *inode* number of the file in the location from which that file is extracted.

The name *c_magic* is based on historical usage.

cpio File Name

For most historical implementations of the *cpio* utility, {PATH_MAX} octets can be used to describe the path name without the addition of any other header fields (the NUL character would be included in this count). {PATH_MAX} is the minimum value for path name size, documented as 256 bytes. However, an implementation may use *c_namesize* to determine the exact length of the path name. With the current description of the **<cpio.h>** header, this path name size can be as large as a number that is described in six octal digits.

Two values are documented under the *c_mode* field values to provide for extensibility for known file types:

Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.

Note that the sockets extension below needs to be integrated, now that sockets have been merged

0110 000 Reserved for contiguous files. The implementation may treat the rest of the information for this archive like a regular file. If this file type is undefined, the implementation may create the file as a regular file.

0140 000 Reserved for sockets. If this type is undefined on the target system, the implementation may decide to ignore this file type and output a warning message.

This provides for extensibility of the *cpio* format while allowing for the ability to read old archives. Files of an unknown type may be read as ''regular files'' on some implementations. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

FUTURE DIRECTIONS

None.

SEE ALSO

cp, *ed*, *getopts*, *printf*, the Base Definitions volume of IEEE Std. 1003.1-200x, **<cpio.h>**, the System Interfaces volume of IEEE Std. 1003.1-200x, *chown*( ), *creat*( ), *mkdir*( ), *stat*( ), *write*( )

CHANGE HISTORY

First released in Issue 4.

Issue 5

A note is added to the APPLICATION USAGE indicating that the *cpio* and *tar* formats can only support files up to 8 gigabytes in size.

Issue 6

The *pax* utility is aligned with the IEEE P1003.2b draft standard:

- Support has been added for symbolic links in the options and interchange formats.
- A new format has been devised, based on extensions to ustar.
- References to the ''extended'' *tar* and *cpio* formats derived from the POSIX.1-1990 standard have been changed to remove the ''extended'' adjective because this could cause confusion with the extended *tar* header added in this revision. (All references to *tar* are actually to **ustar**).

IEEE PASC Interpretation 1003.2 #168 is applied clarifying that *mkdir*( ) and *mkfifo*( ) calls can ignore an [EEXIST] error when extracting an archive.

NAME

pr — print files

SYNOPSIS

```
pr [+page][–column][–adFmrt][–e[char][gap]][–h header][–i[char][gap]]
    [–l lines][–n[char][width]][–o offset][–s[char]][–w width][–fp]
    [file...]
```

DESCRIPTION

The *pr* utility is a printing and pagination filter. If multiple input files are specified, each shall be read, formatted, and written to standard output. By default, the input shall be separated into 66-line pages, each with:

- A 5-line header that includes the page number, date, time, and the path name of the file
- A 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages shall be deferred until the *pr* utility has completed processing.

When options specifying multi-column output are specified, output text columns shall be of equal width; input lines that do not fit into a text column shall be truncated. By default, text columns shall be separated with at least one <blank> character.

OPTIONS

The *pr* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that: the *page* option has a `'+'` delimiter; *page* and *column* can be multi-digit numbers; some of the option-arguments are optional; and some of the option-arguments cannot be specified as separate arguments from the preceding option letter. In particular, the **–s** option does not allow the option letter to be separated from its argument, and the options **–e**, **–i**, and **–n** require that both arguments, if present, not be separated from the option letter.

The following options shall be supported. In the following option descriptions, *column*, *lines*, *offset*, *page*, and *width* are positive decimal integers; *gap* is a non-negative decimal integer.

+*page* Begin output at page number *page* of the formatted input.

–*column* Produce multi-column output that is arranged in *column* columns (the default shall be 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with **–m**. The options **–e** and **–i** shall be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column shall never exceed the length of the page (see the **–l** option). When used with **–t**, use the minimum number of lines to write the output.

–a Modify the effect of the *–column* option so that the columns are filled across the page in a round-robin order (for example, when *column* is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so on).

–d Produce output that is double-spaced; append an extra <newline> character following every <newline> character found in the input.

–e[*char***][***gap***]**
Expand each input <tab> character to the next greater column position specified by the formula *n***gap*+1, where *n* is an integer > 0. If *gap* is zero or is omitted, it shall default to 8. All <tab> characters in the input shall be expanded into the appropriate number of <space> characters. If any non-digit character, *char*, is

specified, it shall be used as the input <tab> character.

XSI **–f** Use a <form-feed> character for new pages, instead of the default behavior that uses a sequence of <newline> characters. Pause before beginning the first page if the standard output is associated with a terminal.

–F Use a <form-feed> character for new pages, instead of the default behavior that uses a sequence of <newline> characters.

–h *header* Use the string *header* to replace the contents of the *file* operand in the page header.

–i[*char***][***gap***]**
In output, replace multiple <space> characters with <tab> characters wherever two or more adjacent <space> characters reach column positions *gap*+1, 2* *gap*+1, 3* *gap*+1, and so on. If *gap* is zero or is omitted, default tab settings at every eighth column position shall be assumed. If any non-digit character, *char*, is specified, it shall be used as the output <tab> character.

–l *lines* Override the 66-line default and reset the page length to *lines*. If *lines* is not greater than the sum of both the header and trailer depths (in lines), the *pr* utility shall suppress both the header and trailer, as if the **–t** option were in effect.

–m Merge files. Standard output shall be formatted so the *pr* utility writes one line from each file specified by a *file* operand, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations shall support merging of at least nine *file* operands.

–n[*char***][***width***]**
Provide *width*-digit line numbering (default for *width* shall be 5). The number shall occupy the first *width* column positions of each text column of default output or each line of **–m** output. If *char* (any non-digit character) is given, it shall be appended to the line number to separate it from whatever follows (default for *char* is a <tab> character).

–o *offset* Each line of output shall be preceded by offset <space>s. If the **–o** option is not specified, the default offset shall be zero. The space taken is in addition to the output line width (see the **–w** option below).

–p Pause before beginning each page if the standard output is directed to a terminal (*pr* shall write an <alert> character to standard error and wait for a <carriage-return> character to be read on **/dev/tty**).

–r Write no diagnostic reports on failure to open files.

–s[*char***]** Separate text columns by the single character *char* instead of by the appropriate number of <space> characters (default for *char* shall be the <tab> character).

–t Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.

–w *width* Set the width of the line to *width* column positions for multiple text-column output only. If the **–w** option is not specified and the **–s** option is not specified, the default width shall be 72. If the **–w** option is not specified and the **–s** option is specified, the default width shall be 512.

For single column output, input lines shall not be truncated.

28458 **OPERANDS**

28459 The following operand shall be supported:

28460 *file* A path name of a file to be written. If no *file* operands are specified, or if a *file*
28461 operand is '–', the standard input shall be used.

28462 **STDIN**

28463 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '–'.
28464 See the INPUT FILES section.

28465 **INPUT FILES**

28466 The input files shall be text files.

28467 The file **/dev/tty** is used to read responses required by the –**p** option.

28468 **ENVIRONMENT VARIABLES**

28469 The following environment variables shall affect the execution of *pr*:

28470 *LANG* Provide a default value for the internationalization variables that are unset or null.
28471 If *LANG* is unset or null, the corresponding value from the implementation-
28472 defined default locale shall be used. If any of the internationalization variables
28473 contains an invalid setting, the utility shall behave as if none of the variables had
28474 been defined.

28475 *LC_ALL* If set to a non-empty string value, override the values of all the other
28476 internationalization variables.

28477 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
28478 characters (for example, single-byte as opposed to multi-byte characters in
28479 arguments and input files) and which characters are defined as printable (character
28480 class **print**). Non-printable characters are still written to standard output, but are
28481 not counted for the purpose for column-width and line-length calculations.

28482 *LC_MESSAGES*

28483 Determine the locale that should be used to affect the format and contents of
28484 diagnostic messages written to standard error.

28485 *LC_TIME* Determine the format of the date and time for use in writing header lines.

28486 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

28487 *TZ* Determine the timezone for use in writing header lines.

28488 **ASYNCHRONOUS EVENTS**

28489 If *pr* receives an interrupt while writing to a terminal, it shall flush all accumulated error
28490 messages to the screen before terminating.

28491 **STDOUT**

28492 The *pr* utility output shall be a paginated version of the original file (or files). This pagination
28493 shall be accomplished using either <form-feed> characters or a sequence of <newline>
28494 XSI characters, as controlled by the –**F** or –**f** option. Page headers shall be generated unless the –**t**
28495 option is specified. The page headers shall be of the form:

28496 `"\n\n%s %s Page %d\n\n\n", <output of date>, <file>, <page number>`

28497 In the POSIX locale, the <*output of date*> field, representing the date and time of last modification
28498 of the input file (or the current date and time if the input file is standard input), shall be
28499 equivalent to the output of the following command as it would appear if executed at the given
28500 time:

```
date "+%b %e %H:%M %Y"
```

without the trailing <newline> character, if the page being written is from standard input. If the page being written is not from standard input, in the POSIX locale, the same format shall be used, but the time used shall be the modification time of the file corresponding to *file* instead of the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the standard input is used instead of a *file* operand, the <*file*> field shall be replaced by a null string.

If the **–h** option is specified, the <*file*> field shall be replaced by the *header* argument.

STDERR

Used for diagnostic messages and for alerting the terminal when **–p** is specified.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Print a numbered list of all files in the current directory:

   ```
   ls –a | pr –n –h "Files in $(pwd)."
   ```

2. Print **file1** and **file2** as a double-spaced, three-column listing headed by ‘‘file list’’:

   ```
   pr –3d –h "file list" file1 file2
   ```

3. Write **file1** on **file2**, expanding tabs to columns 10, 19, 28, . . .:

   ```
   pr –e9 –t <file1 >file2
   ```

RATIONALE

This utility is one of those that does not follow the Utility Syntax Guidelines because of its historical origins. The standard developers could have added new options that obeyed the guidelines (and marked the old options *obsolescent*) or devised an entirely new utility; there are examples of both actions in this volume of IEEE Std. 1003.1-200x. Because of its widespread use by historical applications, the standard developers decided to exempt this version of *pr* from many of the guidelines.

Implementations are required to accept option-arguments to the **–h**, **–l**, **–o**, and **–w** options whether presented as part of the same argument or as a separate argument to *pr*, as suggested by the Utility Syntax Guidelines. The **–n** and **–s** options, however, are specified as in historical practice because they are frequently specified without their optional arguments. If a <blank> were allowed before the option-argument in these cases, a *file* operand could mistakenly be

interpreted as an option-argument in historical applications.

The text about the minimum number of lines in multi-column output was included to ensure that a best effort is made in balancing the length of the columns. There are known historical implementations in which, for example, 60-line files are listed by *pr* –2 as one column of 56 lines and a second of 4. Although this is not a problem when a full page with headers and trailers is produced, it would be relatively useless when used with –**t**.

Historical implementations of the *pr* utility have differed in the action taken for the –**f** option. BSD uses it as described here for the –**F** option; System V uses it to change trailing <newline>s on each page to a <form-feed> and, if standard output is a TTY device, sends an <alert> to standard error and reads a line from **/dev/tty** before the first page. There were strong arguments from both sides of this issue concerning historical practice and additional arguments against the System V –**f** behavior, on the grounds that having the behavior of an option change depending on where output is directed was not a modular design. Therefore, the –**f** option is not specified and the –**F** option has been added.

The <*output of date*> field in the –**l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of IEEE Std. 1003.1-200x, as the appropriate vehicle is a message catalog; that is, the format should be specified as a ‘‘message’’.

FUTURE DIRECTIONS

It is possible that a new interface that conforms to the Utility Syntax Guidelines will be introduced.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The –**p** option is added.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

28575 **NAME**

28576 printf — write formatted output

28577 **SYNOPSIS**

28578 `printf` *format*`[`*argument*`...]`

28579 **DESCRIPTION**

28580 The *printf* utility shall write formatted operands to the standard output. The *argument* operands
28581 shall be formatted under control of the *format* operand.

28582 **OPTIONS**

28583 None.

28584 **OPERANDS**

28585 The following operands shall be supported:

28586 *format* A string describing the format to use to write the remaining operands. See the
28587 EXTENDED DESCRIPTION section.

28588 *argument* The strings to be written to standard output, under the control of *format*. See the
28589 EXTENDED DESCRIPTION section.

28590 **STDIN**

28591 Not used.

28592 **INPUT FILES**

28593 None.

28594 **ENVIRONMENT VARIABLES**

28595 The following environment variables shall affect the execution of *printf*:

28596 *LANG* Provide a default value for the internationalization variables that are unset or null.
28597 If *LANG* is unset or null, the corresponding value from the implementation-
28598 defined default locale shall be used. If any of the internationalization variables
28599 contains an invalid setting, the utility shall behave as if none of the variables had
28600 been defined.

28601 *LC_ALL* If set to a non-empty string value, override the values of all the other
28602 internationalization variables.

28603 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
28604 characters (for example, single-byte as opposed to multi-byte characters in
28605 arguments).

28606 *LC_MESSAGES*

28607 Determine the locale that should be used to affect the format and contents of
28608 diagnostic messages written to standard error.

28609 *LC_NUMERIC*

28610 Determine the locale for numeric formatting. It shall affect the format of numbers
28611 written using the *e*, *E*, *f*, *g*, and *G* conversion characters (if supported).

28612 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

28613 **ASYNCHRONOUS EVENTS**

28614 Default.

STDOUT

See the EXTENDED DESCRIPTION section.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *format* operand shall be used as the *format* string described in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation with the following exceptions:

1. A <space> character in the format string, in any context other than a flag of a conversion specification, shall be treated as an ordinary character that is copied to the output.
2. A `'Δ'` character in the format string shall be treated as a `'Δ'` character, not as a <space> character.
3. In addition to the escape sequences shown in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), `"\ddd"`, where *ddd* is a one, two, or three-digit octal number, shall be written as a byte with the numeric value specified by the octal number.
4. The implementation shall not precede or follow output from the *d* or *u* conversion specifications with <blank> characters not specified by the *format* operand.
5. The implementation shall not precede output from the *o* conversion specification with zeros not specified by the *format* operand.
6. The *e*, *E*, *f*, *g*, and *G* conversion specifications need not be supported.
7. An additional conversion character, *b*, shall be supported as follows. The argument shall be taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences shall be supported:

   — The escape sequences listed in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`), which shall be converted to the characters they represent

   — `"\0ddd"`, where *ddd* is a zero, one, two, or three-digit octal number that shall be converted to a byte with the numeric value specified by the octal number

   — `'\c'`, which shall not be written and shall cause *printf* to ignore any remaining characters in the string operand containing it, any remaining string operands, and any additional characters in the *format* operand

   The interpretation of a backslash followed by any other sequence of characters is unspecified.

   Bytes from the converted string shall be written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it shall be taken to be infinite, so all bytes up to the end of the converted string shall be written.
8. For each specification that consumes an argument, the next argument operand shall be evaluated and converted to the appropriate type for the conversion as specified below.
9. The *format* operand shall be reused as often as necessary to satisfy the argument operands. Any extra *c* or *s* conversion specifications shall be evaluated as if a null string argument were supplied; other extra conversion specifications shall be evaluated as if a zero argument were supplied. If the *format* operand contains no conversion specifications and

argument operands are present, the results are unspecified.

10. If a character sequence in the *format* operand begins with a '%' character, but does not form a valid conversion specification, the behavior is unspecified.

The *argument* operands shall be treated as strings if the corresponding conversion character is *b*, *c*, or *s*; otherwise, it shall be evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign shall be allowed.
- If the leading character is a single-quote or double-quote, the value shall be the numeric value in the underlying codeset of the character following the single-quote or double-quote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message shall be written to standard error and the utility shall not exit with a zero exit status, but shall continue processing any remaining operands and shall write the value accumulated at the time the error was detected to standard output.

It is not considered an error if an argument operand is not completely used for a *c* or *s* conversion or if a string operand's first or second character is used to get the numeric value of a character.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The floating-point formatting conversion specifications of *printf*( ) are not required because all arithmetic in the shell is integer arithmetic. The *awk* utility performs floating-point calculations and provides its own **printf** function. The *bc* utility can perform arbitrary-precision floating-point arithmetic, but does not provide extensive formatting capabilities. (This *printf* utility cannot really be used to format *bc* output; it does not support arbitrary precision.) Implementations are encouraged to support the floating-point conversions as an extension.

Note that this *printf* utility, like the *printf*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x on which it is based, makes no special provision for dealing with multi-byte characters when using the %*c* conversion specification or when a precision is specified in a %*b* or %*s* conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.

No provision is made in this volume of IEEE Std. 1003.1-200x which allows field widths and precisions to be specified as '*' since the '*' can be replaced directly in the *format* operand using shell variable substitution. Implementations can also provide this feature as an extension if they so choose.

Hexadecimal character constants as defined in the ISO C standard are not recognized in the *format* operand because there is no consistent way to detect the end of the constant. Octal character constants are limited to, at most, three octal digits, but hexadecimal character constants are only terminated by a non-hex-digit character. In the ISO C standard, the "##" concatenation operator can be used to terminate a constant and follow it with a hexadecimal character to be written. In the shell, concatenation occurs before the *printf* utility has a chance to

parse the end of the hexadecimal constant.

The %*b* conversion specification is not part of the ISO C standard; it has been added here as a portable way to process backslash escapes expanded in string operands as provided by the *echo* utility. See also the APPLICATION USAGE section of *echo* (on page 2543) for ways to use *printf* as a replacement for all of the traditional versions of the *echo* utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the *printf* utility is required to report an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion shall be reported as errors.

EXAMPLES

To alert the user and then print and read a series of prompts:

```
printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single <tab> character. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
    percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%s%%)\n" \
        $right $wrong $percent
done < database_file
```

The command:

```
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:

```
    1  21
  3214321
54321   0
```

Note that the *format* operand is used three times to print all of the given strings and that a '0' was supplied by *printf* to satisfy the last %4*d* conversion specification.

The *printf* utility is required to notify the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when %*d* is specified as the *format* operand:

Argument	Standard Output	Diagnostic Output
5a	5	**printf: "5a" not completely converted**
9999999999	2147483647	**printf: "9999999999" arithmetic overflow**
−9999999999	−2147483648	**printf: "−9999999999" arithmetic overflow**
ABC	0	**printf: "ABC" expected numeric value**

The diagnostic message format is not specified, but these examples convey the type of information that should be reported. Note that the value shown on standard output is what would be expected as the return value from the *strtol*( ) function as defined in the System Interfaces volume of IEEE Std. 1003.1-200x. A similar correspondence exists between %*u* and *strtoul*( ) and %*e*, %*f*, and %*g* (if the implementation supports floating-point conversions) and *strtod*( ).

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

```
printf "%d\n" 3 +3 –3 \'3 \"+3 "'–3"
```

produces:

3 Numeric value of constant 3

3 Numeric value of constant 3

–3 Numeric value of constant –3

51 Numeric value of the character `'3'` in the ISO/IEC 646:1991 standard codeset

43 Numeric value of the character `'+'` in the ISO/IEC 646:1991 standard codeset

45 Numeric value of the character `'–'` in the ISO/IEC 646:1991 standard codeset

Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the **wchar_t** representation of the character as described in the System Interfaces volume of IEEE Std. 1003.1-200x.

RATIONALE

The *printf* utility was added to provide functionality that has historically been provided by *echo*. However, due to irreconcilable differences in the various versions of *echo* extant, the version has few special features, leaving those to this new *printf* utility, which is based on one in the Ninth Edition system.

The EXTENDED DESCRIPTION section almost exactly matches the *printf*( ) function in the ISO C standard, although it is described in terms of the file format notation in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 5, File Format Notation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

NAME

prs — print an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI `prs [–a][–d dataspec][–r[SID]] file...`

XSI `prs [ –e| –l] –c cutoff [–d dataspec] file...`

XSI `prs [ –e| –l] –r[SID][–d dataspec]file...`

DESCRIPTION

The *prs* utility shall write to standard output parts or all of an SCCS file in a user-supplied format.

OPTIONS

The *prs* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the **–r** option has an optional option-argument. This optional option-argument cannot be presented as a separate argument. The following options shall be supported:

–d *dataspec* Specify the output data specification. The *dataspec* shall be a string consisting of SCCS file *data keywords* (see **Data Keywords** (on page 2956)) interspersed with optional user-supplied text.

–r[*SID***]** Specify the SCCS identification string (SID) of a delta for which information is desired. If no *SID* option-argument is specified, the SID of the most recently created delta is assumed.

–e Request information for all deltas created earlier than and including the delta designated via the **–r** option or the date-time given by the **–c** option.

–l Request information for all deltas created later than and including the delta designated via the **–r** option or the date-time given by the **–c** option.

–c *cutoff* Indicate the *cutoff* date-time, in the form:

*YY***[***MM***[***DD***[***HH***[***MM***[***SS***]]]]]**

For the *YY* component, values in the range [69-99] shall refer to years in the twentieth century (1969 to 1999 inclusive); values in the range [00-68] shall refer to years in the twenty-first century (2000 to 2068 inclusive).

No changes (deltas) to the SCCS file that were created after the specified *cutoff* date-time shall be included in the output. Units omitted from the date-time default to their maximum possible values; for example, **–c 7502** is equivalent to **–c 750228235959**.

–a Request writing of information for both removed, that is, *delta type=R* (see *rmdel* (on page 3037)) and existing, that is, *delta type=D*, deltas. If the **–a** option is not specified, information for existing deltas only shall be provided.

OPERANDS

The following operand shall be supported:

file A path name of an existing SCCS file or a directory. If *file* is a directory, the *prs* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s.**) and unreadable files shall be silently ignored.

If a single instance *file* is specified as '–', the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as '–'. Each line of the text file shall be interpreted as an SCCS path name.

INPUT FILES

Any SCCS files displayed are files of an unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *prs*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file whose format is dependent on the data keywords specified with the **–d** option.

Data Keywords

Data keywords specify which parts of an SCCS file shall be retrieved and output. All parts of an SCCS file have an associated data keyword. A data keyword may appear in a *dataspec* multiple times.

The information written by *prs* consists of:

1. The user-supplied text
2. Appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in the *dataspec*

The format of a data keyword value shall either be simple ('S'), in which keyword substitution is direct, or multi-line ('M').

User-supplied text shall be any text other than recognized data keywords. A <tab> character shall be specified by '\t' and <newline> by '\n'. When the **–r** option is not specified, the default *dataspec* shall be:

```
:PN:\n\n
```

and the following *dataspec* shall be used for each selected delta:

```
:Dt:\t:DL:\nMRs:\n:MR:COMMENTS:\n:C:\n
```

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. The following example:

```
prs –d "User Names for :F: are:\n:UN:" s.file
```

may write to standard output:

```
User Names for s.file are:
xyz
131
abc
```

2. The following example:

```
prs –d "Delta for pgm :M:: :I: – :D: By :P:" –r s.file
```

may write to standard output:

```
Delta for pgm main.c: 3.7 – 77/12/01 By cas
```

3. As a special case:

```
prs s.file
```

may write to standard output:

```
s.file:
<blank line>
D 1.1 77/12/01 00:00:00 cas 1 000000/00000/00000
MRs:
bl78–12345
bl79–54321
COMMENTS:
this is the comment line for s.file initial delta
<blank line>
```

for each delta table entry of the **D** type. The only option allowed to be used with this special case is the **–a** option.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

admin, *delta*, *get*, *what*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Format reorganized.

Exceptions to Utility Syntax Guidelines conformance noted.

Internationalized environment variable support mandated.

Issue 5

The phrase ‘‘in which keyword substitution is followed by a <newline>’’ is deleted from the end of the second paragraph of **Data Keywords** (on page 2956).

The interpretation of the *YY* component of the **–c** *cutoff* argument is noted.

Issue 6

The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements.

NAME

ps — report process status

SYNOPSIS

UP XSI
```
ps [–aA][–defl][–G grouplist][–o format]...[–p proclist][–t termlist]
   [–U userlist][–g grouplist][–n namelist][–u userlist]
```

DESCRIPTION

The *ps* utility shall write information about processes, subject to having the appropriate privileges to obtain information about those processes.

By default, *ps* selects all processes with the same effective user ID as the current user and the same controlling terminal as the invoker.

OPTIONS

The *ps* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–a Write information for all processes associated with terminals. Implementations may omit session leaders from this list.

–A Write information for all processes.

XSI **–d** Write information for all processes, except session leaders.

XSI **–e** Write information for all processes. (Equivalent to **–A**.)

XSI **–f** Generate a **full** listing. (See the STDOUT section for the contents of a **full** listing.)

XSI **–g** *grouplist* Write information for processes whose session leaders are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or comma-separated list.

–G *grouplist* Write information for processes whose real group ID numbers are given in *grouplist*. The application shall ensure that the *grouplist* is a single argument in the form of a <blank> or comma-separated list.

XSI **–l** Generate a **long** listing. (See the STDOUT section for the contents of a **long** listing.)

XSI **–n** *namelist* Specify the name of an alternative system *namelist* file in place of the default. The name of the default file and the format of a *namelist* file are unspecified.

–o *format* Write information according to the format specification given in *format*. This is fully described in the STDOUT section. Multiple **–o** options can be specified; the format specification shall be interpreted as the <space> character-separated concatenation of all the *format* option-arguments.

–p *proclist* Write information for processes whose process ID numbers are given in *proclist*. The application shall ensure that the *proclist* is a single argument in the form of a <blank> or comma-separated list.

–t *termlist* Write information for processes associated with terminals given in *termlist*. The application shall ensure that the *termlist* is a single argument in the form of a <blank> or comma-separated list. Terminal identifiers shall be given in an XSI implementation-defined format. On XSI-conformant systems, they shall be given in one of two forms: the device's file name (for example, **tty04**) or, if the device's

file name starts with **tty**, just the identifier following the characters **tty** (for example, "04").

XSI **–u** *userlist* Write information for processes whose user ID numbers or login names are given in *userlist*. The application shall ensure that the *userlist* is a single argument in the form of a <blank> or comma-separated list. In the listing, the numerical user ID is written unless the **–f** option is used, in which case the login name is written.

–U *userlist* Write information for processes whose real user ID numbers or login names are given in *userlist*. The application shall ensure that the *userlist* is a single argument in the form of a <blank> or comma-separated list.

With the exception of **–o** *format*, all of the options shown are used to select processes. If any are specified, the default list shall be ignored and *ps* shall select the processes represented by the bitwise-inclusive OR of all the selection-criteria options.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ps*:

COLUMNS Override the system-selected horizontal screen size, used to determine the number of text columns to display. See the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LC_TIME Determine the format and contents of the date and time strings displayed.

ASYNCHRONOUS EVENTS

Default.

29069 **STDOUT**

29070 When the –**o** option is not specified, the standard output format is unspecified.

29071 XSI On XSI-conformant systems, the output format is as follows. The column headings and
29072 descriptions of the columns in a *ps* listing are given below. The precise meanings of these fields
29073 are implementation-defined. The letters `'f'` and `'l'` (below) indicate the option (**full** or **long**)
29074 that shall cause the corresponding heading to appear; **all** means that the heading always
29075 appears. Note that these two options determine only what information is provided for a process;
29076 they do not determine which processes are listed.

29077	**F**	(l) Flags (octal and additive) associated with the process.
29078	**S**	(l) The state of the process.
29079	**UID**	(f,l) The user ID number of the process owner; the login name is printed
29080		under the –**f** option.
29081	**PID**	(all) The process ID of the process; it is possible to kill a process if this
29082		datum is known.
29083	**PPID**	(f,l) The process ID of the parent process.
29084	**C**	(f,l) Processor utilization for scheduling.
29085	**PRI**	(l) The priority of the process; higher numbers mean lower priority.
29086	**NI**	(l) Nice value; used in priority computation.
29087	**ADDR**	(l) The address of the process.
29088	**SZ**	(l) The size in blocks of the core image of the process.
29089	**WCHAN**	(l) The event for which the process is waiting or sleeping; if blank, the
29090		process is running.
29091	**STIME**	(f) Starting time of the process.
29092	**TTY**	(all) The controlling terminal for the process.
29093	**TIME**	(all) The cumulative execution time for the process.
29094	**CMD**	(all) The command name; the full command name and its arguments are
29095		written under the –**f** option.

29096 A process that has exited and has a parent, but has not yet been waited for by the parent, is
29097 marked **defunct**.

29098 Under the option –**f**, *ps* tries to determine the command name and arguments given when the
29099 process was created by examining memory or the swap area. Failing this, the command name, as
29100 it would appear without the option –**f**, is written in square brackets.

29101 The –**o** option allows the output format to be specified under user control.

29102 The application shall ensure that the format specification is a list of names presented as a single
29103 argument, <blank> or comma-separated. Each variable has a default header. The default header
29104 can be overridden by appending an equals sign and the new text of the header. The rest of the
29105 characters in the argument shall be used as the header text. The fields specified shall be written
29106 in the order specified on the command line, and should be arranged in columns in the output.
29107 The field widths shall be selected by the system to be at least as wide as the header text (default
29108 or overridden value). If the header text is null, such as –**o** *user*=, the field width shall be at least
29109 as wide as the default header text. If all header text fields are null, no header line shall be
29110 written.

29111 The following names are recognized in the POSIX locale:

29112 **ruser** The real user ID of the process. This shall be the textual user ID, if it can be obtained
29113 and the field width permits, or a decimal representation otherwise.

user The effective user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

rgroup The real group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

group The effective group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.

pid The decimal value of the process ID.

ppid The decimal value of the parent process ID.

pgid The decimal value of the process group ID.

pcpu The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of ''recently'' in this context is unspecified. The CPU time available is determined in an unspecified manner.

vsz The size of the process in (virtual) memory in kilobytes as a decimal integer.

nice The decimal value of the nice value of the process; see *nice* (on page 2872).

etime In the POSIX locale, the elapsed time since the process was started, in the form:

[[*dd*−**]***hh*:**]***mm*:*ss*

where *dd* shall represent the number of days, *hh* the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The *dd* field shall be a decimal integer. The *hh*, *mm*, and *ss* fields shall be two-digit decimal integers padded on the left with zeros.

time In the POSIX locale, the cumulative CPU time of the process in the form:

[*dd*−**]***hh*:*mm*:*ss*

The *dd*, *hh*, *mm*, and *ss* fields shall be as described in the **etime** specifier.

tty The name of the controlling terminal of the process (if any) in the same format used by the *who* utility.

comm The name of the command being executed (*argv*[0] value) as a string.

args The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-defined whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of *ps*.

Any field need not be meaningful in all implementations. In such a case a hyphen (''−'') should be output in place of the field value.

Only **comm** and **args** shall be allowed to contain <blank> characters; all others shall not. Any implementation-defined variables shall be specified in the system documentation along with the default header and indicating if the field may contain <blank> characters.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

29153 **Table 4-17** Variable Names and Default Headers in *ps*

Format Specifier	Default Header	Format Specifier	Default Header
args	**COMMAND**	**ppid**	**PPID**
comm	**COMMAND**	**rgroup**	**RGROUP**
etime	**ELAPSED**	**ruser**	**RUSER**
group	**GROUP**	**time**	**TIME**
nice	**NI**	**tty**	**TT**
pcpu	**%CPU**	**user**	**USER**
pgid	**PGID**	**vsz**	**VSZ**
pid	**PID**		

29163 **STDERR**

29164 Used only for diagnostic messages.

29165 **OUTPUT FILES**

29166 None.

29167 **EXTENDED DESCRIPTION**

29168 None.

29169 **EXIT STATUS**

29170 The following exit values shall be returned:

29171 0 Successful completion.

29172 >0 An error occurred.

29173 **CONSEQUENCES OF ERRORS**

29174 Default.

29175 **APPLICATION USAGE**

29176 Things can change while *ps* is running; the snapshot it gives is only true for an instant, and might
29177 not be accurate by the time it is displayed.

29178 The **args** format specifier is allowed to produce a truncated version of the command arguments.
29179 In some implementations, this information is no longer available when the *ps* utility is executed.

29180 If the field width is too narrow to display a textual ID, the system may use a numeric version.
29181 Normally, the system would be expected to choose large enough field widths, but if a large
29182 number of fields were selected to write, it might squeeze fields to their minimum sizes to fit on
29183 one line. One way to ensure adequate width for the textual IDs is to override the default header
29184 for a field to make it larger than most or all user or group names.

29185 There is no special quoting mechanism for header text. The header text is the rest of the
29186 argument. If multiple header changes are needed, multiple **–o** options can be used, such as:

29187
```
ps –o "user=User Name" –o pid=Process\ ID
```

29188 On some systems, especially multi-level secure systems, *ps* may be severely restricted and
29189 produce information only about child processes owned by the user.

29190 **EXAMPLES**

29191 The command:

29192
```
ps –o user,pid,ppid=MOM –o args
```

29193 writes at least the following in the POSIX locale:

29194
```
  USER   PID   MOM   COMMAND
helene    34    12   ps –o uid,pid,ppid=MOM –o args
```

The contents of the **COMMAND** field need not be the same in all implementations, due to possible truncation.

RATIONALE

There is very little commonality between BSD and System V implementations of *ps*. Many options conflict or have subtly different usages. The standard developers attempted to select a set of options that were useful on a wide range of systems and selected options that either can be implemented on both BSD and System V-based systems without breaking the current implementations or where the options are sufficiently similar that any changes would not be unduly problematic for users or implementors.

It is recognized that on some systems, especially multi-level secure systems, *ps* may be nearly useless. The default output has therefore been chosen such that it does not break historical implementations and also is likely to provide at least some useful information on most systems.

The major change is the addition of the format specification capability. The motivation for this invention is to provide a mechanism for users to access a wider range of system information, if the system permits it, in a portable manner. The fields chosen to appear in this volume of IEEE Std. 1003.1-200x were arrived at after considering what concepts were likely to be both reasonably useful to the ''average'' user and had a reasonable chance of being implemented on a wide range of systems. Again it is recognized that not all systems are able to provide all the information and, conversely, some may wish to provide more. It is hoped that the approach adopted will be sufficiently flexible and extensible to accommodate most systems. Implementations may be expected to introduce new format specifiers.

The default output should consist of a short listing containing the process ID, terminal name, cumulative execution time, and command name of each process.

The preference of the standard developers would have been to make the format specification an operand of the *ps* command. Unfortunately, BSD usage precluded this.

At one time a format was included to display the environment array of the process. This was deleted because there is no portable way to display it.

The **−A** option is equivalent to the BSD **−g** and the SVID **−e**. Because the two systems differed, a mnemonic compromise was selected.

The **−a** option is described with some optional behavior because the SVID omits session leaders, but BSD does not.

In an early proposal, format specifiers appeared for priority and start time. The former was not defined adequately in this volume of IEEE Std. 1003.1-200x and was removed in deference to the defined nice value; the latter because elapsed time was considered to be more useful.

In a new BSD version of *ps*, a **−O** option can be used to write all of the default information, followed by additional format specifiers. This was not adopted because the default output is implementation-defined. Nevertheless, this is a useful option that should be reserved for that purpose. In the **−o** option for the POSIX Shell and Utilities *ps*, the format is the concatenation of each **−o**. Therefore, the user can have an alias or function that defines the beginning of their desired format and add more fields to the end of the output in certain cases where that would be useful.

The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write* require that they all use the same format.

The **pcpu** field indicates that the CPU time available is determined in an unspecified manner. This is because it is difficult to express an algorithm that is useful across all possible machine architectures. Historical counterparts to this value have attempted to show percentage of use in

29242 the recent past, such as the preceding minute. Frequently, these values for all processes did not
29243 add up to 100%. Implementations are encouraged to provide data in this field to users that will
29244 help them identify processes currently affecting the performance of the system.

29245 **FUTURE DIRECTIONS**

29246 None.

29247 **SEE ALSO**

29249 **CHANGE HISTORY**

29250 First released in Issue 2.

29251 **Issue 4**

29252 Aligned with the ISO/IEC 9945-2:1993 standard.

29253 **Issue 6**

29254 This utility is now marked as part of the User Portability Utilities option.

29255 The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

NAME

pwd — return working directory name

SYNOPSIS

```
pwd [–L | –P ]
```

DESCRIPTION

The *pwd* utility shall write to standard output an absolute path name of the current working directory, which does not contain the file names dot or dot-dot.

OPTIONS

The *pwd* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–L If the *PWD* environment variable contains an absolute path name of the current directory that does not contain the file names dot or dot-dot, *pwd* shall write this path name to standard output. Otherwise, the **–L** option shall behave as the **–P** option.

–P The absolute path name written shall not contain file names that, in the context of the path name, refer to files of type symbolic link.

If both **–L** and **–P** are specified, the last one shall apply. If neither **–L** nor **–P** is specified, the *pwd* utility shall behave as if **–L** had been specified.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pwd*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PWD If the **–P** option is in effect, this variable shall be set to an absolute path name of the current working directory that does not contain any components that specify symbolic links, does not contain any components that are dot, and does not contain any components that are dot-dot. If an application sets or unsets the value of *PWD*, the behavior of *pwd* is unspecified.

29299 **ASYNCHRONOUS EVENTS**
29300 Default.

29301 **STDOUT**
29302 The *pwd* utility output is an absolute path name of the current working directory:

29303 `"%s\n", <directory pathname>`

29304 **STDERR**
29305 Used only for diagnostic messages.

29306 **OUTPUT FILES**
29307 None.

29308 **EXTENDED DESCRIPTION**
29309 None.

29310 **EXIT STATUS**
29311 The following exit values shall be returned:

29312 0 Successful completion.

29313 >0 An error occurred.

29314 **CONSEQUENCES OF ERRORS**
29315 If an error is detected, output shall not be written to standard output, a diagnostic message shall
29316 be written to standard error, and the exit status is not zero.

29317 **APPLICATION USAGE**
29318 None.

29319 **EXAMPLES**
29320 None.

29321 **RATIONALE**
29322 Some implementations have historically provided *pwd* as a shell special built-in command.

29323 In most utilities, if an error occurs, partial output may be written to standard output. This does
29324 not happen in historical implementations of *pwd*. Because *pwd* is frequently used in historical
29325 shell scripts without checking the exit status, it is important that the historical behavior is
29326 required here; therefore, the CONSEQUENCES OF ERRORS section specifically disallows any
29327 partial output being written to standard output.

29328 **FUTURE DIRECTIONS**
29329 None.

29330 **SEE ALSO**
29331 *cd*, the System Interfaces volume of IEEE Std. 1003.1-200x, *getcwd*( )

29332 **CHANGE HISTORY**
29333 First released in Issue 2.

29334 **Issue 4**
29335 Aligned with the ISO / IEC 9945-2: 1993 standard.

29336 **Issue 6**
29337 The **–P** and **–L** options are added to describe actions relating to symbolic links as specified in the
29338 IEEE P1003.2b draft standard.

NAME

qalter — alter batch job

SYNOPSIS

BE

```
qalter [–a date_time][–A account_string][–c interval][–e path_name]
    [–h hold_list][–j join_list][–k keep_list][–l resource_list]
    [–m mail_options][–M mail_list][–N name][–o path_name]
    [–p priority][–r y|n][–S path_name_list][–u user_list]
    job_identifier ...
```

DESCRIPTION

The attributes of a batch job are altered by a request to the batch server that manages the batch job. The *qalter* utility is a user-accessible batch client that requests the alteration of the attributes of one or more batch jobs.

The *qalter* utility shall alter the attributes of those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qalter* utility shall alter the attributes of batch jobs in the order in which the batch *job_identifier*s are presented to the utility.

If the *qalter* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

For each batch *job_identifier* for which the *qalter* utility succeeds, each attribute of the identified batch job shall be altered as indicated by all the options presented to the utility.

For each identified batch job for which the *qalter* utility fails, the utility shall not alter any attribute of the batch job.

For each batch job that the *qalter* utility processes, the utility shall not modify any attribute other than those required by the options and option-arguments presented to the utility.

The *qalter* utility shall alter batch jobs by sending a *Modify Job Request* to the batch server that manages each batch job. At the time the *qalter* utility exits, it shall have modified the batch job corresponding to each successfully processed batch *job_identifier*. An attempt to alter the attributes of a batch job in the RUNNING state is implementation-defined.

OPTIONS

The *qalter* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–a *date_time* Redefine the time at which the batch job becomes eligible for execution.

The *qalter* utility shall accept an option-argument that conforms to the syntax of the *date_time* operand of the *touch* utility.

The *qalter* utility shall set the *Execution_Time* attribute of the batch job to the number of seconds since the Epoch that is equivalent to the local time expressed by the value of the *date_time* option-argument. Specifying a *date_time* option-argument that represents a time (number of seconds since the Epoch) earlier than the time at which the utility exits shall have the same effect on batch job execution as if the **–a** option had not been presented to the utility.

–A *account_string*

Redefine the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qalter* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

–**c** *interval* Redefine whether the batch job should be checkpointed, and if so, how often.

The *qalter* utility shall accept a value for the interval option-argument that is one of the following:

n No checkpointing is to be performed on the batch batch job (NO_CHECKPOINT).

s Checkpointing is to be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).

c Automatic periodic checkpointing is to be performed at the *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).

c=minutes Automatic periodic checkpointing is to be performed every *minutes* of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is greater. The *minutes* argument shall conform to the syntax for unsigned integers and shall be greater than zero.

An implementation may define other checkpoint intervals. The conformance document for an implementation shall describe any alternative checkpoint intervals, how they are specified, their internal behavior, and how they affect the behavior of the utility.

The *qalter* utility shall set the *Checkpoint* attribute of the batch job to the value of the *interval* option-argument.

–**e** *path_name* Redefine the path to be used for the standard error stream of the batch job.

The *qalter* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the POSIX.1-1990 standard, which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute path name, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument, including the host name element, if present.

If the *path_name* option-argument constitutes a relative path name and no host name element is specified, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the absolute path name derived by expanding the *path_name* option-argument relative to the current directory of the process that executes the *qalter* utility.

If the *path_name* option-argument constitutes a relative path name and a host name element is specified, the *qalter* utility shall set the *Error_Path* attribute of the batch job to the value of the option-argument without expansion.

If the *path_name* option-argument does not include a host name element, the *qalter* utility shall prefix the path name in the *Error_Path* attribute with *hostname*:, where *hostname* is the name of the host upon which the *qalter* utility is being executed.

–**h** *hold_list* Redefine the types of holds, if any, on the batch job. The *qalter* –**h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters 'u', 's', or 'o', or the single character 'n'. For each unique character in the *hold_list* option-argument, the *qalter* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

u USER

s SYSTEM

o OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored. An existing *Hold_Types* attribute can be cleared by the hold type:

n NO_HOLD

The *qalter* utility shall consider it an error if any hold type other than **n** is combined with hold type **n**. Strictly conforming applications shall not repeat any of the characters 'u', 's', 'o', or 'n' within the *hold_list* option-argument. The *qalter* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

–**j** *join_list* Redefine which streams of the batch job are to be merged. The *qalter* –**j** option shall accept a value for the *join_list* option-argument that is a string of alphanumeric characters in the portable character set.

The *qalter* utility shall accept a *join_list* option-argument that consists of one or more of the characters 'e' and 'o', or the single character 'n'.

All of the other batch job output streams specified shall be merged into the output stream represented by the character listed first in the *join_list* option-argument.

For each unique character in the *join_list* option-argument, the *qalter* utility shall add a value to the *Join_Path* attribute of the batch job as follows, each representing a different batch job stream to join:

e The standard error of the batch batch job (JOIN_STD_ERROR).

o The standard output of the batch batch job (JOIN_STD_OUTPUT).

An existing *Join_Path* attribute can be cleared by the join type:

n NO_JOIN

If **n** is specified, then no files are joined. The *qalter* utility shall consider it an error if any join type other than **n** is combined with join type **n**.

Strictly conforming applications shall not repeat any of the characters 'e', 'o', or 'n' within the *join_list* option-argument. The *qalter* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other join types. The conformance document for an implementation shall describe any additional batch job streams, how they are specified, their internal behavior, and how they affect the behavior of the utility.

29471 –**k** *keep_list* Redefine which output of the batch job to retain on the execution host.

29472 The *qalter* –**k** option shall accept a value for the *keep_list* option-argument that is a
29473 string of alphanumeric characters in the portable character set.

29474 The *qalter* utility shall accept a *keep_list* option-argument that consists of one or
29475 more of the characters `'e'` and `'o'` or the single character `'n'`.

29476 For each unique character in the *keep_list* option-argument, the *qalter* utility shall
29477 add a value to the *Keep_Files* attribute of the batch job as follows, each representing
29478 a different batch job stream to keep:

29479 *e* The standard error of the batch batch job (KEEP_STD_ERROR).

29480 *o* The standard output of the batch batch job (KEEP_STD_OUTPUT).

29481 If both `'e'` and `'o'` are specified, then both files are retained. An existing
29482 *Keep_Files* attribute can be cleared by the keep type:

29483 **n** NO_KEEP

29484 If **n** is specified, then no files are retained. The *qalter* utility shall consider it an error
29485 if any keep type other than **n** is combined with keep type **n**.

29486 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
29487 `'n'` within the *keep_list* option-argument. The *qalter* utility shall permit the
29488 repetition of characters, but shall not assign additional meaning to the repeated
29489 characters. An implementation may define other keep types. The conformance
29490 document for an implementation shall describe any additional keep types, how
29491 they are specified, their internal behavior, and how they affect the behavior of the
29492 utility.

29493 –**l** *resource_list*
29494 Redefine the resources that are allowed or required by the batch job.

29495 The *qalter* utility shall accept a *resource_list* option-argument that conforms to the
29496 following syntax:

29497 `resource=value[,,resource=value,,...]`

29498 The *qalter* utility shall set one entry in the value of the *Resource_List* attribute of the
29499 batch job for each resource listed in the *resource_list* option-argument.

29500 Because the list of supported resource names might vary by batch server, the *qalter*
29501 utility shall rely on the batch server to validate the resource names and associated
29502 values. See Section 3.3.3 (on page 2337) for a means of removing *keyword=value*
29503 (and *value@keyword*) pairs and other general rules for list-oriented batch job
29504 attributes.

29505 –**m** *mail_options*
29506 Redefine the points in the execution of the batch job at which the batch server is to
29507 send mail about a change in the state of the batch job.

29508 The *qalter* –**m** option shall accept a value for the *mail_options* option-argument that
29509 is a string of alphanumeric characters in the portable character set.

29510 The *qalter* utility shall accept a value for the *mail_options* option-argument that is a
29511 string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character
29512 `'n'`. For each unique character in the *mail_options* option-argument, the *qalter*
29513 utility shall add a value to the *Mail_Users* attribute of the batch job as follows, each
29514 representing a different time during the life of a batch job at which to send mail:

29515 *e* MAIL_AT_EXIT

29516 *b* MAIL_AT_BEGINNING

29517 *a* MAIL_AT_ABORT

29518 If any of these characters are duplicated in the *mail_options* option-argument, the
29519 duplicates shall be ignored.

29520 An existing *Mail_Points* attribute can be cleared by the mail type:

29521 **n** NO_MAIL

29522 If **n** is specified, then mail is not sent. The *qalter* utility shall consider it an error if
29523 any mail type other than **n** is combined with mail type **n**. Strictly conforming
29524 applications shall not repeat any of the characters `'e'`, `'b'`, `'a'`, or `'n'` within
29525 the *mail_options* option-argument. The *qalter* utility shall permit the repetition of
29526 characters but shall not assign additional meaning to the repeated characters.

29527 An implementation may define other mail types. The conformance document for
29528 an implementation shall describe any additional mail types, how they are
29529 specified, their internal behavior, and how they affect the behavior of the utility.

29530 –**M** *mail_list* Redefine the list of users to which the batch server that executes the batch job is to
29531 send mail, if the batch server sends mail about the batch job.

29532 The syntax of the *mail_list* option-argument is unspecified. If the implementation
29533 of the *qalter* utility uses a name service to locate users, the utility shall accept the
29534 syntax used by the name service.

29535 If the implementation of the *qalter* utility does not use a name service to locate
29536 users, the implementation shall accept the following syntax for user names:

29537 `mail_address[,,mail_address,,...]`

29538 The interpretation of *mail_address* is implementation-defined.

29539 The *qalter* utility shall set the *Mail_Users* attribute of the batch job to the value of
29540 the *mail_list* option-argument.

29541 –**N** *name* Redefine the name of the batch job.

29542 The *qalter* –**N** option shall accept a value for the *name* option argument that is a
29543 string of up to 15 alphanumeric characters in the portable character set where the
29544 first character is alphabetic.

29545 The syntax of the *name* option-argument is unspecified.

29546 The *qalter* utility shall set the *Job_Name* attribute of the batch job to the value of the
29547 *name* option-argument.

29548 –**o** *path_name* Redefine the path for the standard output of the batch job.

29549 The *qalter* utility shall accept a *path_name* option-argument that conforms to the
29550 syntax of the *path_name* element defined in the POSIX.1-1990 standard, which can
29551 be preceded by a host name element of the form *hostname*:.

29552 If the *path_name* option-argument constitutes an absolute path name, the *qalter*
29553 utility shall set the *Output_Path* attribute of the batch job to the value of the
29554 *path_name* option-argument.

29555 If the *path_name* option-argument constitutes a relative path name and no host
29556 name element is specified, the *qalter* utility shall set the *Output_Path* attribute of the

29557 batch job to the absolute path name derived by expanding the *path_name* option-
29558 argument relative to the current directory of the process that executes the *qalter*
29559 utility.

29560 If the *path_name* option-argument constitutes a relative path name and a host name
29561 element is specified, the *qalter* utility shall set the *Output_Path* attribute of the batch
29562 job to option-argument without any expansion of the path name.

29563 If the *path_name* option-argument does not include a host name element, the *qalter*
29564 utility shall prefix the path name in the *Output_Path* attribute with *hostname*:,
29565 where *hostname* is the name of the host upon which the *qalter* utility is being
29566 executed.

29567 –**p** *priority* Redefine the priority of the batch job.

29568 The *qalter* utility shall accept a value for the priority option-argument that
29569 conforms to the syntax for signed decimal integers, and which is not less than
29570 –1 024 and not greater than 1 023.

29571 The *qalter* utility shall set the *Priority* attribute of the batch job to the value of the
29572 *priority* option-argument.

29573 –**r** *y* | *n* Redefine whether the batch job is rerunable.

29574 If the value of the option-argument is *y*, the *qalter* utility shall set the *Rerunable*
29575 attribute of the batch job to TRUE.

29576 If the value of the option-argument is *n*, the *qalter* utility shall set the *Rerunable*
29577 attribute of the batch job to FALSE.

29578 The *qalter* utility shall consider it an error if any character other than `'y'` or `'n'` is
29579 specified in the option-argument.

29580 –**S** *path_name_list*
29581 Redefine the shell that interprets the script at the destination system.

29582 The *qalter* utility shall accept a *path_name_list* option-argument that conforms to
29583 the following syntax:

29584 `pathname[@host][,pathname[@host],...]`

29585 The *qalter* utility shall accept only one path name that is missing a corresponding
29586 host name. The *qalter* utility shall allow only one path name per named host.

29587 The *qalter* utility shall add a value to the *Shell_Path_List* attribute of the batch job
29588 for each entry in the *path_name_list* option-argument. See Section 3.3.3 (on page
29589 2337) for a means of removing *keyword=value* (and *value@keyword*) pairs and other
29590 general rules for list-oriented batch job attributes.

29591 –**u** *user_list* Redefine the user name under which the batch job is to run at the destination
29592 system.

29593 The *qalter* utility shall accept a *user_list* option-argument that conforms to the
29594 following syntax:

29595 `username[@host][,,username[@host],,...]`

29596 The *qalter* utility shall accept only one user name that is missing a corresponding
29597 host name. The *qalter* utility shall accept only one user name per named host.

29598 The *qalter* utility shall add a value to the *User_List* attribute of the batch job for each
29599 entry in the *user_list* option-argument. See Section 3.3.3 (on page 2337) for a means

of removing *keyword=value* (and *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

OPERANDS

The *qalter* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2336)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qalter*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qalter*.

LOGNAME Determine the login name of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qalter* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qalter* utility attempts to locate the batch job on other batch servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qalter* utility allows users to change the attributes of a batch job.

As a means of altering a queued job, the *qalter* utility is superior to deleting and requeuing the batch job insofar as an altered job retains its place in the queue with some traditional selection algorithms. In addition, the *qalter* utility is both shorter and simpler than a sequence of *qdel* and *qsub* utilities.

The result of an attempt on the part of a user to alter a batch job in a RUNNING state is implementation-defined because a batch job in the RUNNING state will already have opened its output files and otherwise performed any actions indicated by the options in effect at the time the batch job began execution.

The options processed by the *qalter* utility are identical to those of the *qsub* utility, with a few exceptions: **–V**, **–v**, and **–q**. The **–V** and **–v** are inappropriate for the *qalter* utility, since they capture potentially transient environment information from the submitting process. The **–q** option would specify a new queue, which would largely negate the previously stated advantage of using *qalter*; furthermore, the *qmove* utility provides a superior means of moving jobs.

Each of the following paragraphs provides the rationale for a *qalter* option.

Additional rationale concerning these options can be found in the rationale for the *qsub* utility.

The **–a** option allows users to alter the date and time at which a batch job becomes eligible to run.

The **–A** option allows users to change the account that will be charged for the resources consumed by the batch job. Support for the **–A** option is mandatory for conforming implementations of *qalter*, even though support of accounting is optional for servers. Whether or not to support accounting is left to the implementor of the server, but mandatory support of the **–A** option assures users of a consistent interface and allows them to control accounting on servers that support accounting.

The **–c** option allows users to alter the checkpointing interval of a batch job. A checkpointing system, which is not defined by IEEE Std. 1003.1-200x, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of IEEE Std. 1003.1-200x provides the checkpointing interval option. Support for checkpointing is optional for servers.

The **–e** option allows users to alter the name and location of the standard error stream written by a batch job. However, the path of the standard error stream is meaningless if the value of the *Join_Path* attribute of the batch job is TRUE.

The **–h** option allows users to set the hold type in the *Hold_Types* attribute of a batch job. The *qhold* and *qrls* utilities add or remove hold types to the *Hold_Types* attribute, respectively. The **–h**

option has been modified to allow for implementation-defined hold types.

The **–j** option allows users to alter the decision to join (merge) the standard error stream of the batch job with the standard output stream of the batch job.

The **–l** option allows users to change the resource limits imposed on a batch job.

The **–m** option allows users to modify the list of points in the life of a batch job at which the designated users will receive mail notification.

The **–M** option allows users to alter the list of users who will receive notification about events in the life of a batch job.

The **–N** option allows users to change the name of a batch job.

The **–o** option allows users to alter the name and path to which the standard output stream of the batch job will be written.

The **–P** option allows users to modify the priority of a batch job. Support for priority is optional for batch servers.

The **–r** option allows users to alter the rerunability status of a batch job.

The **–S** option allows users to change the name and location of the shell image that will be invoked to interpret the script of the batch job. This option has been modified to allow a list of shell name and locations associated with different host.

The **–u** option allows users to change the user identifier under which the batch job will execute.

The *job_identifier* operand syntax is provided so that the user can differentiate between the originating and destination (or executing) batch server. These may or may not be the same. The *.server_name* portion identifies the originating batch server, while the *@server* portion identifies the destination batch server.

Historically, the *qalter* utility has been a component of the Network Queuing System (NQS), the existing practice from which this utility has been derived.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

29718 **NAME**

29719 qdel — delete batch jobs

29720 **SYNOPSIS**

29721 BE
```
qdel job_identifier ...
```
29722

29723 **DESCRIPTION**

29724 A batch job is deleted by sending a request to the batch server that manages the batch job. A
29725 batch job that has been deleted is no longer subject to management by batch services.

29726 The *qdel* utility is a user-accessible client of batch services that requests the deletion of one or
29727 more batch jobs.

29728 The *qdel* utility shall request a batch server to delete those batch jobs for which a batch
29729 *job_identifier* is presented to the utility.

29730 The *qdel* utility shall delete batch jobs in the order in which their batch *job_identifier*s are
29731 presented to the utility.

29732 If the *qdel* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to
29733 process the remaining batch *job_identifier*s, if any.

29734 The *qdel* utility shall delete each batch job by sending a *Delete Job Request* to the batch server that
29735 manages the batch job.

29736 The *qdel* utility shall not exit until the batch job corresponding to each successfully processed
29737 batch *job_identifier* has been deleted.

29738 **OPTIONS**

29739 None.

29740 **OPERANDS**

29741 The *qdel* utility shall accept one or more operands that conform to the syntax for a batch
29742 *job_identifier* (see Section 3.3.1 (on page 2336)).

29743 **STDIN**

29744 Not used.

29745 **INPUT FILES**

29746 None.

29747 **ENVIRONMENT VARIABLES**

29748 The following environment variables shall affect the execution of *qdel*:

29749 *LANG* Provide a default value for the internationalization variables that are unset or null.
29750 If *LANG* is unset or null, the corresponding value from the implementation- |
29751 defined default locale shall be used. If any of the internationalization variables |
29752 contains an invalid setting, the utility shall behave as if none of the variables had
29753 been defined.

29754 *LC_ALL* If set to a non-empty string value, override the values of all the other
29755 internationalization variables.

29756 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
29757 characters (for example, single-byte as opposed to multi-byte characters in
29758 arguments).

29759 *LC_MESSAGES*
29760 Determine the locale that should be used to affect the format and contents of
29761 diagnostic messages written to standard error.

29762 *LC_TIME* Determine the format and contents of date and time strings written by *qdel*.

29763 *LOGNAME* Determine the login name of the user.

29764 *TZ* Determine the timezone in which the time and date are written. If the *TZ* variable
29765 is not set, an unspecified system default timezone is used.

29766 **ASYNCHRONOUS EVENTS**
29767 Default.

29768 **STDOUT**
29769 An implementation of the *qdel* utility may write informative messages to standard output.

29770 **STDERR**
29771 Used only for diagnostic messages.

29772 **OUTPUT FILES**
29773 None.

29774 **EXTENDED DESCRIPTION**
29775 None.

29776 **EXIT STATUS**
29777 The following exit values shall be returned:

29778 0 Successful completion.

29779 >0 An error occurred.

29780 **CONSEQUENCES OF ERRORS**
29781 In addition to the default behavior, the *qdel* utility shall not be required to write a diagnostic
29782 message to standard error when the error reply received from a batch server indicates that the
29783 batch *job_identifier* does not exist on the server. Whether or not the *qdel* utility waits to output the
29784 diagnostic message while attempting to locate the job on other servers is implementation-
29785 defined.

29786 **APPLICATION USAGE**
29787 None.

29788 **EXAMPLES**
29789 None.

29790 **RATIONALE**
29791 The *qdel* utility allows users and administrators to delete jobs.

29792 The *qdel* utility provides functionality that is not otherwise available. For example, the *kill* utility
29793 of the operating system does not suffice. First, to use the *kill* utility, the user might have to log in
29794 on a remote node, because the *kill* utility does not operate across the network. Second, unlike
29795 *qdel*, *kill* cannot remove jobs from queues. Lastly, the arguments of the *qdel* utility are job
29796 identifiers rather than process identifiers, and so this utility can be passed the output of the
29797 *qselect* utility, thus providing users with a means of deleting a list of jobs.

29798 Because a set of jobs can be selected using the *qselect* utility, the *qdel* utility has not been
29799 complicated with options that provide for selection of jobs. Instead, the batch jobs to be deleted
29800 are identified individually by their job identifiers.

29801 Historically, the *qdel* utility has been a component of NQS, the existing practice on which it is
29802 based. However, the *qdel* utility defined in this volume of IEEE Std. 1003.1-200x does not provide
29803 an option for specifying a signal number to send to the batch job prior to the killing of the
29804 process; that capability has been subsumed by the *qsig* utility.

A discussion was held about the delays of networking and the possibility that the batch server may never respond, due to a down router, down batch server, or other network mishap. The DESCRIPTION records this under the words ‘‘fails to process any job identifier’’. In the broad sense, the network problem is also an error, which causes the failure to process the batch job identifier.

FUTURE DIRECTIONS

None.

kill, *qselect*, *qsig*, Chapter 3 (on page 2313)

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

NAME

qhold — hold batch jobs

SYNOPSIS

BE

```
qhold [–h hold_list] job_identifier ...
```

DESCRIPTION

A hold is placed on a batch job by a request to the batch server that manages the batch job. A batch job that has one or more holds is not eligible for execution. The *qhold* utility is a user-accessible client of batch services that requests one or more types of hold to be placed on one or more batch jobs.

The *qhold* utility shall place holds on those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qhold* utility shall place holds on batch jobs in the order in which their batch *job_identifier*s are presented to the utility. If the *qhold* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qhold* utility shall place holds on each batch job by sending a *Hold Job Request* to the batch server that manages the batch job.

The *qhold* utility shall not exit until holds have been placed on the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qhold* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

–h *hold_list* Define the types of holds to be placed on the batch job.

The *qhold* **–h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

The *qhold* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qhold* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

u USER

s SYSTEM

o OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

n NO_HOLD

The *qhold* utility shall consider it an error if any hold type other than **n** is combined with hold type **n**.

29858 Strictly conforming applications shall not repeat any of the characters 'u', 's',
29859 'o', or 'n' within the *hold_list* option-argument. The *qhold* utility shall permit the
29860 repetition of characters, but shall not assign additional meaning to the repeated
29861 characters.

29862 An implementation may define other hold types. The conformance document for
29863 an implementation shall describe any additional hold types, how they are
29864 specified, their internal behavior, and how they affect the behavior of the utility.

29865 If the **–h** option is not presented to the *qhold* utility, the implementation shall set
29866 the *Hold_Types* attribute to USER.

29867 **OPERANDS**

29868 The *qhold* utility shall accept one or more operands that conform to the syntax for a batch
29869 *job_identifier* (see Section 3.3.1 (on page 2336)).

29870 **STDIN**

29871 Not used.

29872 **INPUT FILES**

29873 None.

29874 **ENVIRONMENT VARIABLES**

29875 The following environment variables shall affect the execution of *qhold*:

29876 *LANG* Provide a default value for the internationalization variables that are unset or null.
29877 If *LANG* is unset or null, the corresponding value from the implementation-
29878 defined default locale shall be used. If any of the internationalization variables
29879 contains an invalid setting, the utility shall behave as if none of the variables had
29880 been defined.

29881 *LC_ALL* If set to a non-empty string value, override the values of all the other
29882 internationalization variables.

29883 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
29884 characters (for example, single-byte as opposed to multi-byte characters in
29885 arguments).

29886 *LC_MESSAGES*
29887 Determine the locale that should be used to affect the format and contents of
29888 diagnostic messages written to standard error.

29889 *LC_TIME* Determine the format and contents of date and time strings written by *qhold*.

29890 *LOGNAME* Determine the login name of the user.

29891 *TZ* Determine the timezone in which the time and date are written. If the *TZ* variable
29892 is not set, an unspecified system default timezone is used.

29893 **ASYNCHRONOUS EVENTS**

29894 Default.

29895 **STDOUT**

29896 None.

29897 **STDERR**

29898 Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qhold* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qhold* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qhold* utility allows users to place a hold on one or more jobs. A hold makes a batch job ineligible for execution.

The *qhold* utility has options that allow the user to specify the type of hold. Should the user wish to place a hold on a set of jobs that meet a selection criteria, such a list of jobs can be acquired using the *qselect* utility.

The **–h** option allows the user to specify the type of hold that is to be placed on the job. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The USER and OPERATOR holds are distinct. The batch server that manages the batch job will verify that the user is authorized to set the specified hold for the batch job.

Mail is not required on hold because the administrator has the tools and libraries to build this option if he or she wishes.

Historically, the *qhold* utility has been a part of some existing batch systems, although it has not traditionally been a part of the NQS.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

29937 **NAME**

29938 qmove — move batch jobs

29939 **SYNOPSIS**

29940 BE
```
qmove destination job_identifier ...
```
29941

29942 **DESCRIPTION**

29943 To move a batch job is to remove the batch job from the batch queue in which it resides and
29944 instantiate the batch job in another batch queue. A batch job is moved by a request to the batch
29945 server that manages the batch job. The *qmove* utility is a user-accessible batch client that requests
29946 the movement of one or more batch jobs.

29947 The *qmove* utility shall move those batch jobs, and only those batch jobs, for which a batch
29948 *job_identifier* is presented to the utility.

29949 The *qmove* utility shall move batch jobs in the order in which the corresponding batch
29950 *job_identifier*s are presented to the utility.

29951 If the *qmove* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to
29952 process the remaining batch *job_identifier*s, if any.

29953 The *qmove* utility shall move batch jobs by sending a *Move Job Request* to the batch server that
29954 manages each batch job. The *qmove* utility shall not exit before the batch jobs corresponding to all
29955 successfully processed batch *job_identifier*s have been moved.

29956 **OPTIONS**

29957 None.

29958 **OPERANDS**

29959 The *qmove* utility shall accept one operand that conforms to the syntax for a *destination* (see
29960 Section 3.3.2 (on page 2337)).

29961 The *qmove* utility shall accept one or more operands that conform to the syntax for a batch
29962 *job_identifier* (see Section 3.3.1 (on page 2336)).

29963 **STDIN**

29964 Not used.

29965 **INPUT FILES**

29966 None.

29967 **ENVIRONMENT VARIABLES**

29968 The following environment variables shall affect the execution of *qmove*:

29969 *LANG* Provide a default value for the internationalization variables that are unset or null.
29970 If *LANG* is unset or null, the corresponding value from the implementation-
29971 defined default locale shall be used. If any of the internationalization variables
29972 contains an invalid setting, the utility shall behave as if none of the variables had
29973 been defined.

29974 *LC_ALL* If set to a non-empty string value, override the values of all the other
29975 internationalization variables.

29976 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
29977 characters (for example, single-byte as opposed to multi-byte characters in
29978 arguments).

29979 *LC_MESSAGES*

29980 Determine the locale that should be used to affect the format and contents of

diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qmove*.

LOGNAME Determine the login name of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qmove* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qmove* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmove* utility allows users to move jobs between queues.

The alternative to using the *qmove* utility—deleting the batch job and requeuing it—entails considerably more typing.

Since the means of selecting jobs based on attributes has been encapsulated in the *qselect* utility, the only option of the *qmove* utility concerns authorization. The **–u** option provides the user with the convenience of changing the user identifier under which the batch job will execute. Minimalism and consistency has taken precedence over convenience; the **–u** option has been deleted because the equivalent capability exists with the **–u** option of the *qalter* utility.

FUTURE DIRECTIONS

None.

30023 **CHANGE HISTORY**

30024 Derived from IEEE Std. 1003.2d-1994.

NAME

qmsg — send message to batch jobs

SYNOPSIS

BE

```
qmsg [–E][–O] message_string job_identifier ...
```

DESCRIPTION

To send a message to a batch job is to request that a server write a message string into one or more output files of the batch job. A message is sent to a batch job by a request to the batch server that manages the batch job. The *qmsg* utility is a user-accessible batch client that requests the sending of messages to one or more batch jobs.

The *qmsg* utility shall write messages into the files of batch jobs by sending a *Job Message Request* to the batch server that manages the batch job. The *qmsg* utility shall not directly write the message into the files of the batch job.

The *qmsg* utility shall send a *Job Message Request* for those batch jobs, and only those batch jobs, for which a batch *job_identifier* is presented to the utility.

The *qmsg* utility shall send *Job Message Request*s for batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qmsg* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qmsg* utility shall not exit before a *Job Message Request* has been sent to the server that manages the batch job that corresponds to each successfully processed batch *job_identifier*.

OPTIONS

The *qmsg* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–E Specify that the message is written to the standard error of each batch job.

The *qmsg* utility shall write the message into the standard error of the batch job.

–O Specify that the message is written to the standard output of each batch job.

The *qmsg* utility shall write the message into the standard output of the batch job.

If neither the **–O** nor the **–E** option is presented to the *qmsg* utility, the utility shall write the message into an implementation-defined file. The conformance document for the implementation shall describe the name and location of the implementation-defined file. If both the **–O** and the **–E** options are presented to the *qmsg* utility, then the utility shall write the messages to both standard output and standard error.

OPERANDS

The *qmsg* utility shall accept a minimum of two operands, *message_string* and one or more batch *job_identifier*s.

The *message_string* operand shall be the string to be written to one or more output files of the batch job followed by a <newline>. If the string contains <blank>s, then the application shall ensure that the string is quoted. The *message_string* shall be encoded in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

All remaining operands are batch *job_identifier*s that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2336)).

30068 **STDIN**

30069 Not used.

30070 **INPUT FILES**

30071 None.

30072 **ENVIRONMENT VARIABLES**

30073 The following environment variables shall affect the execution of *qmsg*:

30074 *LANG* Provide a default value for the internationalization variables that are unset or null.
30075 If *LANG* is unset or null, the corresponding value from the implementation-
30076 defined default locale shall be used. If any of the internationalization variables
30077 contains an invalid setting, the utility shall behave as if none of the variables had
30078 been defined.

30079 *LC_ALL* If set to a non-empty string value, override the values of all the other
30080 internationalization variables.

30081 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
30082 characters (for example, single-byte as opposed to multi-byte characters in
30083 arguments).

30084 *LC_MESSAGES*
30085 Determine the locale that should be used to affect the format and contents of
30086 diagnostic messages written to standard error.

30087 *LC_TIME* Determine the format and contents of date and time strings written by *qmsg*.

30088 *LOGNAME* Determine the login name of the user.

30089 *TZ* Determine the timezone in which the time and date are written. If the *TZ* variable
30090 is not set, an unspecified system default timezone is used.

30091 **ASYNCHRONOUS EVENTS**

30092 Default.

30093 **STDOUT**

30094 None.

30095 **STDERR**

30096 Used only for diagnostic messages.

30097 **OUTPUT FILES**

30098 None.

30099 **EXTENDED DESCRIPTION**

30100 None.

30101 **EXIT STATUS**

30102 The following exit values shall be returned:

30103 0 Successful completion.

30104 >0 An error occurred.

30105 **CONSEQUENCES OF ERRORS**

30106 In addition to the default behavior, the *qmsg* utility shall not be required to write a diagnostic
30107 message to standard error when the error reply received from a batch server indicates that the
30108 batch *job_identifier* does not exist on the server. Whether or not the *qmsg* utility waits to output
30109 the diagnostic message while attempting to locate the job on other servers is implementation-
30110 defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qmsg* utility allows users to write messages into the output files of running jobs. Users, including operators and administrators, have a number of occasions when they want to place messages in the output files of a batch job. For example, if a disk that is being used by a batch job is showing errors, the operator might note this in the standard error stream of the batch job.

The options of the *qmsg* utility provide users with the means of placing the message in the output stream of their choice. The default output stream for the message—if the user does not designate an output stream—is implementation-defined, since many implementations will provide, as an extension to this volume of IEEE Std. 1003.1-200x, a log file that shows the history of utility execution.

If users wish to send a message to a set of jobs that meet a selection criteria, the *qselect* utility can be used to acquire the appropriate list of job identifiers.

The **–E** option allows users to place the message in the standard error stream of the batch job.

The **–O** option allows users to place the message in the standard output stream of the batch job.

Historically, the *qmsg* utility is an existing practice in the offerings of one or more implementors of an NQS-derived batch system. The utility has been found to be useful enough that it deserves to be included in this volume of IEEE Std. 1003.1-200x.

FUTURE DIRECTIONS

None.

NAME

qrerun — rerun batch jobs

SYNOPSIS

BE

```
qrerun job_identifier ...
```

DESCRIPTION

To rerun a batch job is to terminate the session leader of the batch job, delete any associated checkpoint files, and return the batch job to the batch queued state. A batch job is rerun by a request to the batch server that manages the batch job. The *qrerun* utility is a user-accessible batch client that requests the rerunning of one or more batch jobs.

The *qrerun* utility shall rerun those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrerun* utility shall rerun batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrerun* utility fails to process any batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrerun* utility shall rerun batch jobs by sending a *Rerun Job Request* to the batch server that manages each batch job.

For each successfully processed batch *job_identifier*, the *qrerun* utility shall have rerun the corresponding batch batch job at the time the utility exits.

OPTIONS

None.

OPERANDS

The *qrerun* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2336)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrerun*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qrerun*.

LOGNAME Determine the login name of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qrerun* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qrerun* utility waits to output the diagnostic message while attempting to locate the job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qrerun* utility allows users to cause jobs in the running state to exit and rerun.

The *qrerun* utility is a new utility, *vis-a-vis* existing practice, that has been defined in this volume of IEEE Std. 1003.1-200x to correct user-perceived deficiencies in the existing practice.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

NAME

qrls — release batch jobs

SYNOPSIS

BE

```
qrls [–h hold_list] job_identifier ...
```

DESCRIPTION

A batch job might have one or more holds, which prevent the batch job from executing. A batch job from which all the holds have been removed becomes eligible for execution and is said to have been released. A batch job hold is removed by sending a request to the batch server that manages the batch job. The *qrls* utility is a user-accessible client of batch services that requests holds be removed from one or more batch jobs.

The *qrls* utility shall remove one or more holds from those batch jobs for which a batch *job_identifier* is presented to the utility.

The *qrls* utility shall remove holds from batch jobs in the order in which their batch *job_identifier*s are presented to the utility.

If the *qrls* utility fails to process a batch *job_identifier* successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

The *qrls* utility shall remove holds on each batch job by sending a *Release Job Request* to the batch server that manages the batch job.

The *qrls* utility shall not exit until the holds have been removed from the batch job corresponding to each successfully processed batch *job_identifier*.

OPTIONS

The *qrls* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:

–h *hold_list* Define the types of holds to be removed from the batch job.

The *qrls* **–h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

The *qrls* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

For each unique character in the *hold_list* option-argument, the *qrls* utility shall add a value to the *Hold_Types* attribute of the batch job as follows, each representing a different hold type:

u USER

s SYSTEM

o OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

An existing *Hold_Types* attribute can be cleared by the following hold type:

n NO_HOLD

The *qrls* utility shall consider it an error if any hold type other than **n** is combined with hold type **n**.

Strictly conforming applications shall not repeat any of the characters 'u', 's', 'o', or 'n' within the *hold_list* option-argument. The *qrls* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the –**h** option is not presented to the *qrls* utility, the implementation shall remove the USER hold in the *Hold_Types* attribute.

OPERANDS

The *qrls* utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2336)).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qrls*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qrls*.

LOGNAME Determine the login name of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

None.

30302 **STDERR**

30303 Used only for diagnostic messages.

30304 **OUTPUT FILES**

30305 None.

30306 **EXTENDED DESCRIPTION**

30307 None.

30308 **EXIT STATUS**

30309 The following exit values shall be returned:

30310 0 Successful completion.

30311 >0 An error occurred.

30312 **CONSEQUENCES OF ERRORS**

30313 In addition to the default behavior, the *qrls* utility shall not be required to write a diagnostic
30314 message to standard error when the error reply received from a batch server indicates that the
30315 batch *job_identifier* does not exist on the server. Whether or not the *qrls* utility waits to output the
30316 diagnostic message while attempting to locate the job on other servers is implementation-
30317 defined.

30318 **APPLICATION USAGE**

30319 None.

30320 **EXAMPLES**

30321 None.

30322 **RATIONALE**

30323 The *qrls* utility allows users, operators, and administrators to remove holds from jobs.

30324 The *qrls* utility does not support any job selection options or wildcard arguments. Users may
30325 acquire a list of jobs selected by attributes using the *qselect* utility. For example, a user could
30326 select all of their held jobs.

30327 The **–h** option allows the user to specify the type of hold that is to be removed. This option
30328 allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The batch
30329 server that manages the batch job will verify whether the user is authorized to remove the
30330 specified hold for the batch job. If more than one type of hold has been placed on the batch job, a
30331 user may wish to remove only some of them.

30332 Mail is not required on release because the administrator has the tools and libraries to build this
30333 option if required.

30334 The *qrls* utility is a new utility *vis-a-vis* existing practice; it has been defined in this volume of
30335 IEEE Std. 1003.1-200x as the natural complement to the *qhold* utility.

30336 **FUTURE DIRECTIONS**

30337 None.

30338 **SEE ALSO**

30339 *qhold*, *qselect*, Chapter 3 (on page 2313)

30340 **CHANGE HISTORY**

30341 Derived from IEEE Std. 1003.2d-1994.

NAME

qselect — select batch jobs

SYNOPSIS

BE

```
qselect [–a [op]date_time][–A account_string][–c [op]interval]
    [–h hold_list][–l resource_list][–N name][–p [op]priority]
    [–q destination][–r y|n][–s states][–u user_list]
```

DESCRIPTION

To select a set of batch jobs is to return the batch *job_identifier*s for each batch job that meets a list of selection criteria. A set of batch jobs is selected by a request to a batch server. The *qselect* utility is a user-accessible batch client that requests the selection of batch jobs.

Upon successful completion, the *qselect* utility shall have returned a list of zero or more batch *job_identifier*s that meet the criteria specified by the options and option-arguments presented to the utility.

The *qselect* utility shall select batch jobs by sending a *Select Jobs Request* to a batch server. The *qselect* utility shall not exit until the server replies to each request generated.

For each option presented to the *qselect* utility, the utility shall restrict the set of selected batch jobs as described in the OPTIONS section.

The *qselect* utility shall not restrict selection of batch jobs except by authorization and as required by the options presented to the utility.

When an option is specified with a mandatory or optional *op* component to the option-argument, then *op* shall specify a relation between the value of a certain batch job attribute and the *value* component of the option-argument. If an *op* is allowable on an option, then the description of the option letter indicates the *op* as either mandatory or optional. Acceptable strings for the *op* component, and the relation the string indicates, are shown in the following list:

`.eq.` The value represented by the attribute of the batch job is equal to the value represented by the option-argument.

`.ge.` The value represented by the attribute of the batch job is greater than or equal to the value represented by the option-argument.

`.gt.` The value represented by the attribute of the batch job is greater than the value represented by the option-argument.

`.lt.` The value represented by the attribute of the batch job is less than the value represented by the option-argument.

`.le.` The value represented by the attribute of the batch job is less than or equal to the value represented by the option-argument.

`.ne.` The value represented by the attribute of the batch job is not equal to the value represented by the option-argument.

OPTIONS

The *qselect* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–a [*op***]***date_time*
Restrict selection to a specific time, or a range of times.

The *qselect* utility shall select only batch jobs for which the value of the *Execution_Time* attribute is related to the Epoch equivalent of the local time expressed by the value of the *date_time* component of the option-argument in the manner indicated by the value of the *op* component of the option-argument.

The *qselect* utility shall accept a *date_time* component of the option-argument that conforms to the syntax of the *date_time* operand of the *touch* utility.

If the *op* component of the option-argument is not presented to the *qselect* utility, the utility shall select batch jobs for which the *Execution_Time* attribute is equal to the *date_time* component of the option-argument.

When comparing times, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.` The time represented by value of the *Execution_Time* attribute of the batch job is equal the time represented by the *date_time* component of the option-argument.

`.ge.` The time represented by value of the *Execution_Time* attribute of the batch job is after or equal to the time represented by the *date_time* component of the option-argument.

`.gt.` The time represented by value of the *Execution_Time* attribute of the batch job is after the time represented by the *date_time* component of the option-argument.

`.lt.` The time represented by value of the *Execution_Time* attribute of the batch job is before the time represented by the *date_time* component of the option-argument.

`.le.` The time represented by value of the *Execution_Time* attribute of the batch job is before or equal to the time represented by the *date_time* component of the option-argument.

`.ne.` The time represented by value of the *Execution_Time* attribute of the batch job is not equal to the time represented by the *date_time* component of the option-argument.

The *qselect* utility shall accept the defined character strings for the *op* component of the option-argument.

–A *account_string*

Restrict selection to the batch jobs charging a specified account.

The *qselect* utility shall select only batch jobs for which the value of the *Account_Name* attribute of the batch job matchs the value of the *account_string* option-argument.

The syntax of the *account_string* option-argument is unspecified.

–c [*op***]***interval*

Restrict selection to batch jobs within a range of checkpoint intervals.

The *qselect* utility shall select only batch jobs for which the value of the *Checkpoint* attribute relates to the value of the *interval* component of the option-argument in the manner indicated by the value of the *op* component of the option-argument.

If the *op* component of the option-argument is omitted, the *qselect* utility shall select batch jobs for which the value of the *Checkpoint* attribute is equal to the value

of the *interval* component of the option-argument.

When comparing checkpoint intervals, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

`.eq.` The value of the *Checkpoint* attribute of the batch job equals the value of the *interval* component of the option-argument.

`.ge.` The value of the *Checkpoint* attribute of the batch job is greater than or equal to the value of the *interval* component option-argument.

`.gt.` The value of the *Checkpoint* attribute of the batch job is greater than the value of the *interval* component option-argument.

`.lt.` The value of the *Checkpoint* attribute of the batch job is less than the value of the *interval* component option-argument.

`.le.` The value of the *Checkpoint* attribute of the batch job is less than or equal to the value of the *interval* component option-argument.

`.ne.` The value of the *Checkpoint* attribute of the batch job does not equal the value of the *interval* component option-argument.

The *qselect* utility shall accept the defined character strings for the *op* component of the option-argument.

The ordering relationship for the values of the interval option-argument is defined to be:

`'n' .gt. 's' .gt. 'c=`*`minutes`*`' .ge. 'c'`

When comparing *Checkpoint* attributes with an interval having the value of the single character `'u'`, only equality or inequality are valid comparisons.

–**h** *hold_list* Restrict selection to batch jobs that have a specific type of hold.

The *qselect* utility shall select only batch jobs for which the value of the *Hold_Types* attribute matches the value of the *hold_list* option-argument.

The *qselect* –**h** option shall accept a value for the *hold_list* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

The *qselect* utility shall accept a value for the *hold_list* option-argument that is a string of one or more of the characters `'u'`, `'s'`, or `'o'`, or the single character `'n'`.

Each unique character in the *hold_list* option-argument of the *qselect* utility is defined as follows, each representing a different hold type:

u USER

s SYSTEM

o OPERATOR

If any of these characters are duplicated in the *hold_list* option-argument, the duplicates shall be ignored.

The *qselect* utility shall consider it an error if any hold type other than **n** is combined with hold type **n**.

Strictly conforming applications shall not repeat any of the characters 'u', 's', 'o', or 'n' within the *hold_list* option-argument. The *qselect* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

–l *resource_list*

Restrict selection to batch jobs with specified resource limits and attributes.

The *qselect* utility shall accept a *resource_list* option-argument with the following syntax:

resource_name op value **[**,,*resource_name op value*,, ...**]**

When comparing resource values, the *qselect* utility shall use the following definitions for the *op* component of the option-argument:

.eq. The value of the resource of the same name in the *Resource_List* attribute of the batch job equals the value of the value component of the option-argument.

.ge. The value of the resource of the same name in the *Resource_List* attribute of the batch job is greater than or equal to the value of the *value* component of the option-argument.

.gt. The value of the resource of the same name in the *Resource_List* attribute of the batch job is greater than the value of the value component of the option-argument.

.lt. The value of the resource of the same name in the *Resource_List* attribute of the batch job is less than the value of the value component of the option-argument.

.ne. The value of the resource of the same name in the *Resource_List* attribute of the batch job does not equal the value of the value component of the option-argument.

.le. The value of the resource of the same name in the *Resource_List* attribute of the batch job is less than or equal to the value of the *value* component of the option-argument.

When comparing the limit of a *Resource_List* attribute with the *value* component of the option-argument, if the limit, the value, or both are non-numeric, only equality or inequality are valid comparisons.

The *qselect* utility shall select only batch jobs for which the values of the *resource_name*s listed in the *resource_list* option-argument match the corresponding limits of the *Resource_List* attribute of the batch job.

Limits of *resource_name*s present in the *Resource_List* attribute of the batch job that have no corresponding values in the *resource_list* option-argument shall not be considered when selecting batch jobs.

–N *name* Restrict selection to batch jobs with a specified name.

The *qselect* utility shall select only batch jobs for which the value of the *Job_Name* attribute matches the value of the *name* option-argument. The string specified in

30514 the *name* option-argument shall be passed, uninterpreted, to the server. This allows
30515 an implementation to match ''wildcard'' patterns against batch job names.

30516 An implementation shall describe in the conformance document the format it
30517 supports for matching against the *Job_Name* attribute.

30518 **−p [***op***]***priority*

30519 Restrict selection to batch jobs of the specified priority or range of priorities.

30520 The *qselect* utility shall select only batch jobs for which the value of the *Priority*
30521 attribute of the batch job relates to the value of the *priority* component of the
30522 option-argument in the manner indicated by the value of the *op* component of the
30523 option-argument.

30524 If the *op* component of the option-argument is omitted, the *qselect* utility shall
30525 select batch jobs for which the value of the *Priority* attribute of the batch job is
30526 equal to the value of the *priority* component of the option-argument.

30527 When comparing priority values, the *qselect* utility shall use the following
30528 definitions for the *op* component of the option-argument:

30529 `.eq.` The value of the *Priority* attribute of the batch job equals the value of the
30530 *priority* component of the option-argument.

30531 `.ge.` The value of the *Priority* attribute of the batch job is greater than or equal
30532 to the value of the *priority* component option-argument.

30533 `.gt.` The value of the *Priority* attribute of the batch job is greater than the value
30534 of the *priority* component option-argument.

30535 `.lt.` The value of the *Priority* attribute of the batch job is less than the value of
30536 the *priority* component option-argument.

30537 `.lt.` The value of the *Priority* attribute of the batch job is less than or equal to
30538 the value of the *priority* component option-argument.

30539 `.ne.` The value of the *Priority* attribute of the batch job does not equal the value
30540 of the *priority* component option-argument.

30541 **−q** *destination*

30542 Restrict selection to the specified batch queue or server, or both.

30543 The *qselect* utility shall select only batch jobs that are located at the destination
30544 indicated by the value of the *destination* option-argument.

30545 The destination defines a batch queue, a server, or a batch queue at a server.

30546 The *qselect* utility shall accept an option-argument for the **−q** option that conforms
30547 to the syntax for a destination. If the **−q** option is not presented to the *qselect* utility,
30548 the utility shall select batch jobs from all batch queues at the default batch server.

30549 If the option-argument describes only a batch queue, the *qselect* utility shall select
30550 only batch jobs from the batch queue of the specified name at the default batch
30551 server. The means by which *qselect* determines the default server is
30552 implementation-defined.

30553 If the option-argument describes only a batch server, the *qselect* utility shall select
30554 batch jobs from all the batch queues at that batch server.

30555 If the option-argument describes both a batch queue and a batch server, the *qselect*
30556 utility shall select only batch jobs from the specified batch queue at the specified

server.

–**r** *y* | *n* Restrict selection to batch jobs with the specified rerunability status.

The *qselect* utility shall select only batch jobs for which the value of the *Rerunable* attribute of the batch job matches the value of the option-argument.

The *qselect* utility shall accept a value for the option-argument that consists of either the single character `'y'` or the single character `'n'`. The character `'y'` represents the value TRUE, and the character `'n'` represents the value FALSE.

–**s** *states* Restrict selection to batch jobs in the specified states.

The *qselect* utility shall accept an option-argument that consists of any combination of the characters `'e'`, `'q'`, `'r'`, `'w'`, `'h'`, and `'t'`.

Conforming applications shall not repeat any character in the option-argument. The *qselect* utility shall permit the repetition of characters in the option-argument, but shall not assign additional meaning to repeated characters.

The *qselect* utility shall interpret the characters in the *states* option-argument as follows:

`e` Represents the EXITING state.

`q` Represents the QUEUED state.

`r` Represents the RUNNING state.

`t` Represents the TRANSITING state.

`h` Represents the HELD state.

`w` Represents the WAITING state.

For each character in the *states* option-argument, the *qselect* utility shall select batch jobs in the corresponding state.

–**u** *user_list* Restrict selection to batch jobs owned by the specified user names.

The *qselect* utility shall select only the batch jobs of those users specified in the *user_list* option-argument.

The *qselect* utility shall accept a *user_list* option-argument that conforms to the following syntax:

username`[`@*host*`][,,`*username*`[`@*host*`],, ...]`

The *qselect* utility shall accept only one user name that is missing a corresponding host name. The *qselect* utility shall accept only one user name per named host.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

30594 **ENVIRONMENT VARIABLES**

30595 The following environment variables shall affect the execution of *qselect*:

30596 *LANG* Provide a default value for the internationalization variables that are unset or null.
30597 If *LANG* is unset or null, the corresponding value from the implementation-
30598 defined default locale shall be used. If any of the internationalization variables
30599 contains an invalid setting, the utility shall behave as if none of the variables had
30600 been defined.

30601 *LC_ALL* If set to a non-empty string value, override the values of all the other
30602 internationalization variables.

30603 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
30604 characters (for example, single-byte as opposed to multi-byte characters in
30605 arguments).

30606 *LC_MESSAGES*
30607 Determine the locale that should be used to affect the format and contents of
30608 diagnostic messages written to standard error.

30609 *LC_TIME* Determine the format and contents of date and time strings written by *qselect*.

30610 *LOGNAME* Determine the login name of the user.

30611 *TZ* Determine the timezone in which the time and date are written. If the *TZ* variable
30612 is not set, an unspecified system default timezone is used.

30613 **ASYNCHRONOUS EVENTS**

30614 Default.

30615 **STDOUT**

30616 The *qselect* utility shall write zero or more batch *job_identifier*s to standard output.

30617 The *qselect* utility shall separate the batch *job_identifier*s written to standard output by white
30618 space.

30619 The *qselect* utility shall write batch *job_identifier*s in the following format:

30620 *sequence_number.server_name@server*

30621 **STDERR**

30622 Used only for diagnostic messages.

30623 **OUTPUT FILES**

30624 None.

30625 **EXTENDED DESCRIPTION**

30626 None.

30627 **EXIT STATUS**

30628 The following exit values shall be returned:

30629 0 Successful completion.

30630 >0 An error occurred.

30631 **CONSEQUENCES OF ERRORS**

30632 Default.

30633 **APPLICATION USAGE**

30634 None.

30635 **EXAMPLES**

30636 The following example shows how a user might use the *qselect* utility in conjunction with the
30637 *qdel* utility to delete all of his or her jobs in the queued state without affecting any jobs that are
30638 already running:

30639 ```
qdel $(qselect –s q)
```

30640 or:

30641 ```
qselect –s q || xargs qdel
```

30642 **RATIONALE**

30643 The *qselect* utility allows users to acquire a list of job identifiers that match user-specified
30644 selection criteria. The list of identifiers returned by the *qselect* utility conforms to the syntax of
30645 the batch job identifier list processed by a utility such as *qmove*, *qdel*, and *qrls*.The *qselect* utility is
30646 thus a powerful tool for causing another batch system utility to act upon a set of jobs that match
30647 a list of selection criteria.

30648 The options of the *qselect* utility let the user apply a number of useful filters for selecting jobs.
30649 Each option further restricts the selection of jobs. Many of the selection options allow the
30650 specification of a relational operator. The FORTRAN-like syntax of the operator—that is,
30651 `".lt."`, was chosen rather than the C-like `"<="` meta-characters.

30652 The **–a** option allows users to restrict the selected jobs to those that have been submitted (or
30653 altered) to wait until a particular time. The time period is determined by the argument of this
30654 option, which includes both a time and an operator—it is thus possible to select jobs waiting
30655 until a specific time, jobs waiting until after a certain time, or those waiting for a time before the
30656 specified time.

30657 The **–A** option allows users to restrict the selected jobs to those that have been submitted (or
30658 altered) to charge a particular account.

30659 The **–c** option allows users to restrict the selected jobs to those whose checkpointing interval
30660 falls within the specified range.

30661 The **–l** option allows users to select those jobs whose resource limits fall within the range
30662 indicated by the value of the option. For example, a user could select those jobs for which the
30663 CPU time limit is greater than two hours.

30664 The **–N** option allows users to select jobs by job name. For instance, all the parts of a task that
30665 have been divided in parallel jobs might be given the same name, and thus manipulated as a
30666 group by means of this option.

30667 The **–q** option allows users to select jobs in a specified queue.

30668 The **–r** option allows users to select only those jobs with a specified rerun criteria. For instance, a
30669 user might select only those jobs that can be rerun for use with the *qrerun* utility.

30670 The **–s** option allows users to select only those jobs that are in a certain state.

30671 The **–u** option allows users to select jobs that have been submitted to execute under a particular
30672 account.

30673 The selection criteria provided by the options of the *qselect* utility allow users to select jobs based |
30674 on all the appropriate attributes that can be assigned to jobs by the *qsub* utility. When
30675 implementors extend the *qsub* utility, or another utilities, using the **–W** option, they may likewise
30676 elect to extend the *qselect* utility to allow additional selection criteria.

Historically, the *qselect* utility has not been a part of existing practice; it is an improvement that has been introduced in this volume of IEEE Std. 1003.1-200x.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

30685 **NAME**

30686 qsig — signal batch jobs

30687 **SYNOPSIS**

30688 BE
```
qsig [–s signal] job_identifier ...
```
30689

30690 **DESCRIPTION**

30691 To signal a batch job is to send a signal to the session leader of the batch job. A batch job is
30692 signaled by sending a request to the batch server that manages the batch job. The *qsig* utility is a
30693 user-accessible batch client that requests the signaling of a batch job.

30694 The *qsig* utility shall signal those batch jobs for which a batch *job_identifier* is presented to the
30695 utility. The *qsig* utility shall not signal any batch jobs whose batch *job_identifier*s are not
30696 presented to the utility.

30697 The *qsig* utility shall signal batch jobs in the order in which the corresponding batch
30698 *job_identifier*s are presented to the utility. If the *qsig* utility fails to process a batch *job_identifier*
30699 successfully, the utility shall proceed to process the remaining batch *job_identifier*s, if any.

30700 The *qsig* utility shall signal batch jobs by sending a *Signal Job Request* to the batch server that
30701 manages the batch job.

30702 For each successfully processed batch *job_identifier*, the *qsig* utility shall have received a
30703 completion reply to each *Signal Job Request* sent to a batch server at the time the utility exits.

30704 **OPTIONS**

30705 The *qsig* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section |
30706 12.2, Utility Syntax Guidelines. |

30707 The following option shall be supported by the implementation:

30708 **–s** *signal* Define the signal to be sent to the batch job.

30709 The *qsig* utility shall accept a *signal* option-argument that is either a symbolic
30710 signal name or an unsigned integer signal number (see the POSIX.1-1990 standard,
30711 Section 3.3.1.1). The *qsig* utility shall accept signal names for which the SIG prefix
30712 has been omitted.

30713 If the *signal* option-argument is a signal name, the *qsig* utility shall send that name.

30714 If the *signal* option-argument is a number, the *qsig* utility shall send the signal
30715 value represented by the number.

30716 If the **–s** option is not presented to the *qsig* utility, the utility shall send the signal
30717 SIGTERM to each signaled batch job.

30718 **OPERANDS**

30719 The *qsig* utility shall accept one or more operands that conform to the syntax for a batch
30720 *job_identifier* (see Section 3.3.1 (on page 2336)).

30721 **STDIN**

30722 Not used.

30723 **INPUT FILES**

30724 None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qsig*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qsig*.

LOGNAME Determine the login name of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

An implementation of the *qsig* utility may write informative messages to standard output.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qsig* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qsig* utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementation-defined.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The *qsig* utility allows users to signal batch jobs.

A user may be unable to signal a batch job with the *kill* utility of the operating system for a number of reasons. First, the process ID of the batch job may be unknown to the user. Second, the processes of the batch job may be on a remote node. However, by virtue of communication between batch nodes, the *qsig* utility can arrange for the signaling of a process.

Because a batch job that is not running cannot be signaled, and because the signal may not terminate the batch job, the *qsig* utility is not a substitute for the *qdel* utility.

The options of the *qsig* utility allow the user to specify the signal that is to be sent to the batch job.

The **–s** option allows users to specify a signal by name or by number, and thus override the default signal. The POSIX.1-1990 standard defines signals by both name and number.

The *qsig* utility is a new utility, *vis-a-vis* existing practice; it has been defined in this volume of IEEE Std. 1003.1-200x in response to user-perceived shortcomings in existing practice.

FUTURE DIRECTIONS

None.

kill, *qdel*, Chapter 3 (on page 2313)

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

NAME

qstat — show status of batch jobs

SYNOPSIS

BE

```
qstat [–f] job_identifier ...
qstat –Q [–f] destination ...
qstat –B [–f] server_name ...
```

DESCRIPTION

The status of a batch job, batch queue, or batch server is obtained by a request to the server. The *qstat* utility is a user-accessible batch client that requests the status of one or more batch jobs, batch queues, or servers, and writes the status information to standard output.

For each successfully processed batch *job_identifier*, the *qstat* utility shall display information about the corresponding batch job.

For each successfully processed destination, the *qstat* utility shall display information about the corresponding batch queue.

For each successfully processed server name, the *qstat* utility shall display information about the corresponding server.

The *qstat* utility shall acquire batch job status information by sending a *Job Status Request* to a batch server. The *qstat* utility shall acquire batch queue status information by sending a *Queue Status Request* to a batch server. The *qstat* utility shall acquire server status information by sending a *Server Status Request* to a batch server.

OPTIONS

The *qstat* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:

–f Specify that a full display is produced.

The minimum contents of a full display are specified in the STDOUT section.

Additional contents and format of a full display are implementation-defined.

–Q Specify that the operand is a destination.

The *qstat* utility shall display information about each batch queue at each destination identified as an operand.

–B Specify that the operand is a server name.

The *qstat* utility shall display information about each server identified as an operand.

OPERANDS

If the **–Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a destination (see Section 3.3.2 (on page 2337)).

If the **–B** option is presented to the *qstat* utility, the utility shall accept one or more *server_name* operands.

If neither the **–B** nor the **–Q** option is presented to the *qstat* utility, the utility shall accept one or more operands that conform to the syntax for a batch *job_identifier* (see Section 3.3.1 (on page 2336)).

30830 **STDIN**

30831 Not used.

30832 **INPUT FILES**

30833 None.

30834 **ENVIRONMENT VARIABLES**

30835 The following environment variables shall affect the execution of *qstat*:

30836 *COLUMNS* Override the system-selected horizontal screen size. See the Base Definitions |
30837 volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid |
30838 values and results when it is unset or null.

30839 *HOME* Determine the path name of the user's home directory.

30840 *LANG* Provide a default value for the internationalization variables that are unset or null.
30841 If *LANG* is unset or null, the corresponding value from the implementation- |
30842 defined default locale shall be used. If any of the internationalization variables |
30843 contains an invalid setting, the utility shall behave as if none of the variables had
30844 been defined.

30845 *LC_ALL* If set to a non-empty string value, override the values of all the other
30846 internationalization variables.

30847 *LC_COLLATE*
30848 Determine the locale for the behavior of ranges, equivalence classes and multi-
30849 character collating elements within regular expressions.

30850 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
30851 characters (for example, single-byte as opposed to multi-byte characters in
30852 arguments).

30853 *LC_MESSAGES*
30854 Determine the locale that should be used to affect the format and contents of
30855 diagnostic messages written to standard error.

30856 *LC_NUMERIC*
30857 Determine the locale for selecting the radix character used when writing floating-
30858 point formatted output.

30859 *LC_TIME* Determine the format and contents of date and time strings written by *qstat*.

30860 *LINES* Override the system-selected vertical screen size, used as the number of lines in a
30861 screenful and the vertical screen size in visual mode. See the Base Definitions |
30862 volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables for valid |
30863 values and results when it is unset or null. |

30864 *LOGNAME* Determine the login name of the user.

30865 *TERM* Determine the terminal type. If this variable is unset or null, and if the **–T** option is
30866 not specified, an unspecified default terminal type shall be used.

30867 *TZ* Determine the timezone in which the time and date are written. If the *TZ* variable
30868 is not set, an unspecified system default timezone is used.

30869 **ASYNCHRONOUS EVENTS**

30870 Default.

30871 **STDOUT**

30872 If an operand presented to the *qstat* utility is a batch *job_identifier* and the **–f** option is not
30873 specified, the *qstat* utility shall display the following items on a single line, in the stated order,
30874 with white space between each item, for each successfully processed operand:

30875 • The batch *job_identifier*

30876 • The batch job name

30877 • The *Job_Owner* attribute

30878 • The CPU time used by the batch job

30879 • The batch job state

30880 • The batch job location

30881 If an operand presented to the *qstat* utility is a batch *job_identifier* and the **–f** option is specified,
30882 the *qstat* utility shall display the following items for each success fully processed operand:

30883 • The batch *job_identifier*

30884 • The batch job name

30885 • The *Job_Owner* attribute

30886 • The execution user ID

30887 • The CPU time used by the batch job

30888 • The batch job state

30889 • The batch job location

30890 • Additional implementation-defined information, if any, about the batch job or batch queue |

30891 If an operand presented to the *qstat* utility is a destination, the **–Q** option is specified, and the **–f**
30892 option is not specified, the *qstat* utility shall display the following items on a single line, in the
30893 stated order, with white space between each item, for each successfully processed operand:

30894 • The batch queue name

30895 • The maximum number of batch jobs that are allowed to run in the batch queue concurrently

30896 • The total number of batch jobs in the batch queue

30897 • The status of the batch queue

30898 • For each state, the number of batch jobs in that state in the batch queue and the name of the
30899 state

30900 • The type of batch queue (execution or routing)

30901 If the operands presented to the *qstat* utility are destinations, the **–Q** option is specified, and the
30902 **–f** option is specified, the *qstat* utility shall display the following items for each successfully
30903 processed operand:

30904 • The batch queue name

30905 • The maximum number of batch jobs that are allowed to run in the batch queue concurrently

30906 • The total number of batch jobs in the batch queue

30907 • The status of the batch queue

- For each state, the number of batch jobs in that state in the batch queue and the name of the state
- The type of batch queue (execution or routing)
- Additional implementation-defined information, if any, about the batch queue

If the operands presented to the *qstat* utility are batch server names, the **–B** option is specified, and the **–f** option is not specified, the *qstat* utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch server name
- The maximum number of batch jobs that are allowed to run in the batch queue concurrently
- The total number of batch jobs managed by the batch server
- The status of the batch server
- For each state, the number of batch jobs in that state and the name of the state

If the operands presented to the *qstat* utility are server names, the **–B** option is specified, and the **–f** option is specified, the *qstat* utility shall display the following items for each successfully processed operand:

- The server name
- The maximum number of batch jobs that are allowed to run in the batch queue concurrently
- The total number of batch jobs managed by the server
- The status of the server
- For each state, the number of batch jobs in that state and the name of the state
- Additional implementation-defined information, if any, about the server

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

In addition to the default behavior, the *qstat* utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch *job_identifier* does not exist on the server. Whether or not the *qstat* utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementation-defined.

30946 **APPLICATION USAGE**

30947 None.

30948 **EXAMPLES**

30949 None.

30950 **RATIONALE**

30951 The *qstat* utility allows users to display the status of jobs and listing the batch jobs in queues.

30952 The operands of the *qstat* utility may be either job identifiers, queues (specified as destination
30953 identifiers), or batch server names. The **–Q** and **–B** options, or absence thereof, indicate the
30954 nature of the operands.

30955 The other options of the *qstat* utility allow the user to control the amount of information
30956 displayed and the format in which it is displayed. Should a user wish to display the status of a
30957 set of jobs that match a selection criteria, the *qselect* utility may be used to acquire such a list.

30958 The **–f** option allows users to request a ‘‘full’’ display in an implementation-defined format. |

30959 Historically, the *qstat* utility has been a part of the NQS and its derivatives, the existing practice |
30960 on which it is based.

30961 **FUTURE DIRECTIONS**

30962 None.

30963 **SEE ALSO**

30964 *qselect*, Chapter 3 (on page 2313)

30965 **CHANGE HISTORY**

30966 Derived from IEEE Std. 1003.2d-1994.

30967 **NAME**

30968 qsub — submit a script

30969 **SYNOPSIS**

30970 BE
```
qsub [–a date_time][–A account_string][–c interval]
    [–C directive_prefix][–e path_name][–h][–j join_list][–k keep_list]
    [–m mail_options][–M mail_list][–N name]
    [–o path_name][–p priority][–q destination][–r y|n]
    [–S path_name_list][–u user_list][–v variable_list][–V]
    [–z][script]
```

30976

30977 **DESCRIPTION**

30978 To submit a script is to create a batch job that executes the script. A script is submitted by a
30979 request to a batch server. The *qsub* utility is a user-accessible batch client that submits a script.

30980 Upon successful completion, the *qsub* utility shall have created a batch job that will execute the
30981 submitted script.

30982 The *qsub* utility shall submit a script by sending a *Queue Job Request* to a batch server.

30983 The *qsub* utility shall place the value of the following environment variables in the *Variable_List*
30984 attribute of the batch job: *HOME*, *LANG*, *LOGNAME*, *PATH*, *MAIL*, *SHELL*, and *TZ*. The name
30985 of the environment variable shall be the current name prefixed with the string PBS_O_.

30986 **Note:** If the current value of the *HOME* variable in the environment space of the *qsub* utility
30987 is **/aa/bb/cc**, then *qsub* shall place *PBS_O_HOME*=**/aa/bb/cc** in the *Variable_List*
30988 attribute of the batch job.

30989 In addition to the variables described above, the *qsub* utility shall add the following variables
30990 with the indicated values to the variable list:

30991 *PBS_O_WORKDIR* The absolute path of the current working directory of the *qsub* utility process.

30992 *PBS_O_HOST* The name of the host on which the *qsub* utility is running.

30993 **OPTIONS**

30994 The *qsub* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
30995 12.2, Utility Syntax Guidelines.

30996 The following options shall be supported by the implementation:

30997 **–a** *date_time* Define the time at which a batch job becomes eligible for execution.

30998 The *qsub* utility shall accept an option-argument that conforms to the syntax of the
30999 *date_time* operand of the *touch* utility.

Table 4-18 Environment Variable Values (Utilities)

Variable Name	Value at qsub Time
PBS_O_HOME	*HOME*
PBS_O_HOST	Client host name
PBS_O_LANG	*LANG*
PBS_O_LOGNAME	*LOGNAME*
PBS_O_PATH	*PATH*
PBS_O_MAIL	*MAIL*
PBS_O_SHELL	*SHELL*
PBS_O_TZ	*TZ*
PBS_O_WORKDIR	Current working directory

Note: The server that initiates execution of the batch job will add other variables to the batch job's environment; see Section 3.2.2.1 (on page 2319).

The *qsub* utility shall set the *Execution_Time* attribute of the batch job to the number of seconds since the Epoch that is equivalent to the local time expressed by the value of the *date_time* option-argument. The Epoch is defined in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.151, Epoch.

If the **−a** option is not presented to the *qsub* utility, the utility shall set the *Execution_Time* attribute of the batch job to a time (number of seconds since the Epoch) that is earlier than the time at which the utility exits.

−A *account_string*

Define the account to which the resource consumption of the batch job should be charged.

The syntax of the *account_string* option-argument is unspecified.

The *qsub* utility shall set the *Account_Name* attribute of the batch job to the value of the *account_string* option-argument.

If the **−A** option is not presented to the *qsub* utility, the utility shall omit the *Account_Name* attribute from the attributes of the batch job.

−c *interval* Define whether the batch job should be checkpointed, and if so, how often.

The *qsub* utility shall accept a value for the interval option-argument that is one of the following:

n No checkpointing shall be performed on the batch batch job (NO_CHECKPOINT).

s Checkpointing shall be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).

c Automatic periodic checkpointing shall be performed at the *Minimum_Cpu_Interval* attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).

c=minutes Automatic periodic checkpointing shall be performed every minutes of CPU time, or every *Minimum_Cpu_Interval* minutes, whichever is greater. The *minutes* argument shall conform to the syntax for unsigned integers and shall be greater than zero.

The *qsub* utility shall set the *Checkpoint* attribute of the batch job to the value of the *interval* option-argument.

If the **–c** option is not presented to the *qsub* utility, the utility shall set the *Checkpoint* attribute of the batch job to the single character 'u' (CHECKPOINT_UNSPECIFIED).

–C *directive_prefix*
Define the prefix that declares a directive to the *qsub* utility within the script.

The *directive_prefix* is not a batch job attribute; it affects the behavior of the *qsub* utility.

If the **–C** option is presented to the *qsub* utility, and the value of the *directive_prefix* option-argument is the null string, the utility shall not scan the script file for directives. If the **–C** option is not presented to the *qsub* utility, then the value of the *PBS_DPREFIX* environment variable is used. If the environment variable is not defined, then #PBS encoded in the portable character set is the default.

–e *path_name* Define the path to be used for the standard error stream of the batch job.

The *qsub* utility shall accept a *path_name* option-argument which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute path name, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument.

If the *path_name* option-argument constitutes a relative path name and no host name element is specified, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the absolute path name derived by expanding the *path_name* option-argument relative to the current directory of the process executing *qsub*.

If the *path_name* option-argument constitutes a relative path name and a host name element is specified, the *qsub* utility shall set the *Error_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion. The host name element shall be included.

If the *path_name* option-argument does not include a host name element, the *qsub* utility shall prefix the path name with *hostname*:, where *hostname* is the name of the host upon which the *qsub* utility is being executed.

If the **–e** option is not presented to the *qsub* utility, the utility shall set the *Error_Path* attribute of the batch job to the host name and path of the current directory of the submitting process and the default file name.

The default file name for standard error has the following format:

job_name.e*sequence_number*

–h Specify that a USER hold is applied to the batch job.

The *qsub* utility shall set the value of the *Hold_Types* attribute of the batch job to the value USER.

If the **–h** option is not presented to the *qsub* utility, the utility shall set the *Hold_Types* attribute of the batch job to the value NO_HOLD.

–j *join_list* Define which streams of the batch job are to be merged. The *qsub* **–j** option shall accept a value for the *join_list* option-argument that is a string of alphanumeric

31087 characters in the portable character set (see the Base Definitions volume of
31088 IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

31089 The *qsub* utility shall accept a *join_list* option-argument that consists of one or
31090 more of the characters `'e'` and `'o'` or the single character `'n'`.

31091 All of the other batch job output streams specified will be merged into the output
31092 stream represented by the character listed first in the *join_list* option-argument.

31093 For each unique character in the *join_list* option-argument, the *qsub* utility shall
31094 add a value to the *Join_Path* attribute of the batch job as follows, each representing
31095 a different batch job stream to join:

31096 *e* The standard error of the batch batch job (JOIN_STD_ERROR).

31097 *o* The standard output of the batch batch job (JOIN_STD_OUTPUT).

31098 An existing *Join_Path* attribute can be cleared by the following join type:

31099 **n** NO_JOIN

31100 If **n** is specified, then no files are joined. The *qsub* utility shall consider it an error if
31101 any join type other than **n** is combined with join type **n**.

31102 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
31103 `'n'` within the *join_list* option-argument. The *qsub* utility shall permit the
31104 repetition of characters, but shall not assign additional meaning to the repeated
31105 characters.

31106 An implementation may define other join types. The conformance document for an
31107 implementation shall describe any additional batch job streams, how they are
31108 specified, their internal behavior, and how they affect the behavior of the utility.

31109 If the **–j** option is not presented to the *qsub* utility, the utility shall set the value of
31110 the *Join_Path* attribute of the batch job to NO_JOIN.

31111 **–k** *keep_list* Define which output of the batch job to retain on the execution host.

31112 The *qsub* **–k** option shall accept a value for the *keep_list* option-argument that is a
31113 string of alphanumeric characters in the portable character set (see the Base
31114 Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

31115 The *qsub* utility shall accept a *keep_list* option-argument that consists of one or
31116 more of the characters `'e'` and `'o'` or the single character `'n'`.

31117 For each unique character in the *keep_list* option-argument, the *qsub* utility shall
31118 add a value to the *Keep_Files* attribute of the batch job as follows, each representing
31119 a different batch job stream to keep:

31120 *e* The standard error of the batch batch job (KEEP_STD_ERROR).

31121 *o* The standard output of the batch batch job (KEEP_STD_OUTPUT).

31122 If both *e* and *o* are specified, then both files are retained. An existing *Keep_Files*
31123 attribute can be cleared by the following keep type:

31124 **n** NO_KEEP

31125 If **n** is specified, then no files are retained. The *qsub* utility shall consider it an error
31126 if any keep type other than **n** is combined with keep type **n**.

31127 Strictly conforming applications shall not repeat any of the characters `'e'`, `'o'`, or
31128 `'n'` within the *keep_list* option-argument. The *qsub* utility shall permit the

repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other keep types. The conformance document for an implementation shall describe any additional keep types, how they are specified, their internal behavior, and how they affect the behavior of the utility. If the −**k** option is not presented to the *qsub* utility, the utility shall set the *Keep_Files* attribute of the batch job to the value NO_KEEP.

−**m** *mail_options*

Define the points in the execution of the batch job at which the batch server that manages the batch job shall send mail about a change in the state of the batch job.

The *qsub* −**m** option shall accept a value for the *mail_options* option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set).

The *qsub* utility shall accept a value for the *mail_options* option-argument that is a string of one or more of the characters `'e'`, `'b'`, and `'a'`, or the single character `'n'`.

For each unique character in the *mail_options* option-argument, the *qsub* utility shall add a value to the *Mail_Users* attribute of the batch job as follows, each representing a different time during the life of a batch job at which to send mail:

e MAIL_AT_EXIT

b MAIL_AT_BEGINNING

a MAIL_AT_ABORT

If any of these characters are duplicated in the *mail_options* option-argument, the duplicates shall be ignored.

An existing *Mail_Points* attribute can be cleared by the following mail type:

n NO_MAIL

If **n** is specified, then mail is not sent. The *qsub* utility shall consider it an error if any mail type other than **n** is combined with mail type **n**.

Strictly conforming applications shall not repeat any of the characters `'e'`, `'b'`, `'a'`, or `'n'` within the *mail_options* option-argument.

The *qsub* utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other mail types. The conformance document for an implementation shall describe any additional mail types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the −**m** option is not presented to the *qsub* utility, the utility shall set the *Mail_Points* attribute to the value MAIL_AT_ABORT.

−**M** *mail_list* Define the list of users to which a batch server that executes the batch job shall send mail, if the server sends mail about the batch job.

The syntax of the *mail_list* option-argument is unspecified.

If the implementation of the *qsub* utility uses a name service to locate users, the utility should accept the syntax used by the name service.

If the implementation of the *qsub* utility does not use a name service to locate users, the implementation should accept the following syntax for user names:

mail_address[,,*mail_address*,, ...]

The interpretation of *mail_address* is implementation-defined.

The *qsub* utility shall set the *Mail_Users* attribute of the batch job to the value of the *mail_list* option-argument.

If the −**M** option is not presented to the *qsub* utility, the utility shall place only the user name and host name for the current process in the *Mail_Users* attribute of the batch job.

−**N** *name* Define the name of the batch job.

The *qsub* −**N** option shall accept a value for the *name* option-argument that is a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.

The *qsub* utility shall set the value of the *Job_Name* attribute of the batch job to the value of the *name* option-argument.

If the −**N** option is not presented to the *qsub* utility, the utility shall set the *Job_Name* attribute of the batch job to the name of the *script* argument from which the directory specification if any, has been removed.

If the −**N** option is not presented to the *qsub* utility, and the script is read from standard input, the utility shall set the *Job_Name* attribute of the batch job to the value STDIN.

−**o** *path_name* Define the path for the standard output of the batch job.

The *qsub* utility shall accept a *path_name* option-argument that conforms to the syntax of the *path_name* element defined in the POSIX.1-1990 standard, which can be preceded by a host name element of the form *hostname*:.

If the *path_name* option-argument constitutes an absolute path name, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

If the *path_name* option-argument constitutes a relative path name and no host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the path name derived by expanding the value of the *path_name* option-argument relative to the current directory of the process executing the *qsub*.

If the *path_name* option-argument constitutes a relative path name and a host name element is specified, the *qsub* utility shall set the *Output_Path* attribute of the batch job to the value of the *path_name* option-argument without expansion.

If the *path_name* option-argument does not specify a host name element, the *qsub* utility shall prefix the path name with *hostname*:, where *hostname* is the name of the host upon which the *qsub* utility is executing.

If the −**o** option is not presented to the *qsub* utility, the utility shall set the *Output_Path* attribute of the batch job to the host name and path of the current directory of the submitting process and the default file name.

The default file name for standard output has the following format:

31214 *job_name*.o*sequence_number*

31215 –**p** *priority* Define the priority the batch job should have relative to other batch jobs owned by
31216 the batch server.

31217 The *qsub* utility shall set the *Priority* attribute of the batch job to the value of the
31218 *priority* option-argument.

31219 If the –**p** option is not presented to the *qsub* utility, the value of the *Priority* |
31220 attribute is implementation-defined. |

31221 The *qsub* utility shall accept a value for the *priority* option-argument that conforms
31222 to the syntax for signed decimal integers, and which is not less than –1 024 and not
31223 greater than 1 023.

31224 –**q** *destination*
31225 Define the destination of the batch job.

31226 The destination is not a batch job attribute; it determines the batch server, and
31227 possibly the batch queue, to which the *qsub* utility batch queues the batch job.

31228 The *qsub* utility shall submit the script to the batch server named by the *destination*
31229 option-argument or the server that owns the batch queue named in the *destination*
31230 option-argument.

31231 The *qsub* utility shall accept an option-argument for the –**q** option that conforms to
31232 the syntax for a destination (see Section 3.3.2 (on page 2337)).

31233 If the –**q** option is not presented to the *qsub* utility, the *qsub* utility shall submit the
31234 batch job to the default destination. The mechanism for determining the default
31235 destination is implementation-defined. |

31236 –**r** *y* | *n* Define whether the batch job is rerunable.

31237 If the value of the option-argument is *y*, the *qsub* utility shall set the *Rerunable* |
31238 attribute of the batch job to TRUE.

31239 If the value of the option-argument is *n*, the *qsub* utility shall set the *Rerunable* |
31240 attribute of the batch job to FALSE.

31241 If the –**r** option is not presented to the *qsub* utility, the utility shall set the *Rerunable*
31242 attribute of the batch job to TRUE.

31243 –**S** *path_name_list*
31244 Define the path name to the shell under which the batch job is to execute.

31245 The *qsub* utility shall accept a *path_name_list* option-argument that conforms to the
31246 following syntax:

31247 *pathname*[@*host*][,,*pathname*[@*host*],, ...]

31248 The *qsub* utility shall allow only one path name for a given host name. The *qsub*
31249 utility shall allow only one path name that is missing a corresponding host name.

31250 The *qsub* utility shall add a value to the *Shell_Path_List* attribute of the batch job for
31251 each entry in the *path_name_list* option-argument.

31252 If the –**S** option is not presented to the *qsub* utility, the utility shall set the
31253 *Shell_Path_List* attribute of the batch job to the null string.

31254 The conformance document for an implementation shall describe the mechanism
31255 used to set the default shell and determine the current value of the default shell.

31256 An implementation shall provide a means for the installation to set the default
31257 shell to the login shell of the user under which the batch job is to execute. See
31258 Section 3.3.3 (on page 2337) for a means of removing *keyword=value* (and
31259 *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

31260 **–u** *user_list* Define the user name under which the batch job is to execute.

31261 The *qsub* utility shall accept a *user_list* option-argument that conforms to the
31262 following syntax:

31263 *username*`[@`*host*`][,,`*username*`[@`*host*`],, ...]`

31264 The *qsub* utility shall accept only one user name that is missing a corresponding
31265 host name. The *qsub* utility shall accept only one user name per named host.

31266 The *qsub* utility shall add a value to the *User_List* attribute of the batch job for each
31267 entry in the *user_list* option-argument.

31268 If the **–u** option is not presented to the *qsub* utility, the utility shall set the *User_List*
31269 attribute of the batch job to the user name from which the utility is executing. See
31270 Section 3.3.3 (on page 2337) for a means of removing *keyword=value* (and
31271 *value@keyword*) pairs and other general rules for list-oriented batch job attributes.

31272 **–v** *variable_list*
31273 Add to the list of variables that are exported to the session leader of the batch job.

31274 A *variable_list* is a set of strings of either the form <*variable*> or <*variable=value*>,
31275 delimited by commas.

31276 If the **–v** option is presented to the *qsub* utility, the utility shall also add, to the
31277 environment *Variable_List* attribute of the batch job, every variable named in the
31278 environment *variable_list* option-argument and, optionally, values of specified
31279 variables.

31280 If a value is not provided on the command line, the *qsub* utility shall set the value
31281 of each variable in the environment *Variable_List* attribute of the batch job to the
31282 value of the corresponding environment variable for the process in which the
31283 utility is executing; see Table 4-18 (on page 3013).

31284 A conforming application shall not repeat a variable in the environment
31285 *variable_list* option-argument.

31286 The *qsub* utility shall not repeat a variable in the environment *Variable_List*
31287 attribute of the batch job. See Section 3.3.3 (on page 2337) for a means of removing
31288 *keyword=value* (and *value@keyword*) pairs and other general rules for list-oriented
31289 batch job attributes.

31290 **–V** Specify that all of the environment variables of the process are exported to the
31291 context of the batch job.

31292 The *qsub* utility shall place every environment variable in the process in which the
31293 utility is executing in the list and shall set the value of each variable in the attribute
31294 to the value of that variable in the process.

31295 **–z** Specify that the utility does not write the batch *job_identifier* of the created batch
31296 job to standard output.

31297 If the **–z** option is presented to the *qsub* utility, the utility shall not write the batch
31298 *job_identifier* of the created batch job to standard output.

If the **–z** option is not presented to the *qsub* utility, the utility shall write the identifier of the created batch job to standard output.

OPERANDS

The *qsub* utility shall accept a *script* operand that indicates the path to the script of the batch job.

If the *script* operand is not presented to the *qsub* utility, or if the operand is the single-character string `'-'`, the utility shall read the script from standard input.

If the script represents a partial path, the *qsub* utility shall expand the path relative to the current directory of the process executing the utility.

STDIN

The *qsub* utility reads the script of the batch job from standard input if the script operand is omitted or is the single character `'-'`.

INPUT FILES

In addition to binding the file indicated by the *script* operand to the batch job, the *qsub* utility reads the script file and acts on directives in the script.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *qsub*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings written by *qsub*.

LOGNAME Determine the login name of the user.

PBS_DPREFIX
Determine the default prefix for directives within the script.

SHELL Determine the path name of the preferred command language interpreter of the user.

TZ Determine the timezone in which the time and date are written. If the *TZ* variable is not set, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

Once created, a batch job exists until it exits, aborts, or is deleted.

After a batch job is created by the *qsub* utility, batch servers might route, execute, modify, or delete the batch job.

STDOUT

The *qsub* utility writes the batch *job_identifier* assigned to the batch job to standard output, unless the **–z** option is specified.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

Script Preservation

The *qsub* utility shall make the script available to the server executing the batch job in such a way that the server executes the script as it exists at the time of submission.

The *qsub* utility can send a copy of the script to the server with the *Queue Job Request* or store a temporary copy of the script in a location specified to the server.

Option Specification

A script can contain directives to the *qsub* utility.

The *qsub* utility shall scan the lines of the script for directives, skipping blank lines, until the first line that begins with a string other than the directive string; if directives occur on subsequent lines, the utility shall ignore those directives.

Lines are separated by a <newline>. If the first line of the script begins with "#!" or a colon (':'), then it is skipped. The *qsub* utility shall process a line in the script as a directive if and only if the string of characters from the first non-white-space character on the line until the first <space> or <tab> character on the line match the directive prefix. If a line in the script contains a directive and the final characters of the line are backslash ('\') and <newline>, then the next line shall be interpreted as a continuation of that directive.

The *qsub* utility shall process the options and option-arguments contained on the directive prefix line using the same syntax as if the options were input on the *qsub* utility.

The *qsub* utility shall continue to process a directive prefix line until after a <newline> is encountered. An implementation may ignore lines which, according to the syntax of the shell that will interpret the script, are comments. An implementation shall describe in the conformance document the format of any shell comments that it will recognize.

If an option is present in both a directive and the arguments to the *qsub* utility, the utility shall ignore the option and the corresponding option-argument, if any, in the directive.

If an option that is present in the directive is not present in the arguments to the *qsub* utility, the utility shall process the option and the option-argument, if any.

In order of preference, the *qsub* utility shall select the directive prefix from one of the following sources:

- If the **–C** option is presented to the utility, the value of the *directive_prefix* option-argument
- If the environment variable *PBS_DPREFIX* is defined, the value of that variable
- The four-character string "#PBS" encoded in the portable character set

If the **–C** option is present in the script file it shall be ignored.

31380 **EXIT STATUS**

31381 The following exit values shall be returned:

31382 0 Successful completion.

31383 >0 An error occurred.

31384 **CONSEQUENCES OF ERRORS**

31385 Default.

31386 **APPLICATION USAGE**

31387 None.

31388 **EXAMPLES**

31389 None.

31390 **RATIONALE**

31391 The *qsub* utility allows users to create a batch job that will process the script specified as the
31392 operand of the utility.

31393 The options of the *qsub* utility allow users to control many aspects of the queuing and execution
31394 of a batch job.

31395 The **–a** option allows users to designate the time after which the batch job will become eligible to
31396 run. By specifying an execution time, users can take advantage of resources at off-peak hours,
31397 synchronize jobs with chronologically predictable events, and perhaps take advantage of off-
31398 peak pricing of computing time. For these reasons and others, a timing option is existing practice
31399 on the part of almost every batch system, including NQS.

31400 The **–A** option allows users to specify the account that will be charged for the batch job. Support
31401 for account is not mandatory for conforming batch servers.

31402 The **–C** option allows users to prescribe the prefix for directives within the script file. The default
31403 prefix "#PBS" may be inappropriate if the script will be interpreted with an alternate shell, as
31404 specified by the **–S** option.

31405 The **–c** option allows users to establish the checkpointing interval for their jobs. A checkpointing
31406 system, which is not defined by this volume of IEEE Std. 1003.1-200x, allows recovery of a batch
31407 job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs
31408 that consume expensive computing time or must meet a critical schedule. Users should be
31409 allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely
31410 completion of the batch job; therefore, this volume of IEEE Std. 1003.1-200x provides the
31411 checkpointing interval option. Support for checkpointing is optional for batch servers.

31412 The **–e** option allows users to redirect the standard error streams of their jobs to a non-default
31413 path. For example, if the submitted script generally produces a great deal of useless error output,
31414 a user might redirect the standard error output to the null device. Or, if the file system holding
31415 the default location (the home directory of the user) has too little free space, the user might
31416 redirect the standard error stream to a file in another file system.

31417 The **–h** option allows users to create a batch job that is held until explicitly released. The ability
31418 to create a held job is useful when some external event must complete before the batch job can
31419 execute. For example, the user might submit a held job and release it when the system load has
31420 dropped.

31421 The **–j** option allows users to merge the standard error of a batch job into its standard output
31422 stream, which has the advantage of showing the sequential relationship between output and
31423 error messages.

The **–m** option allows users to designate those points in the execution of a batch job at which mail will be sent to the submitting user, or to the account(s) indicated by the **–M** option. By requesting mail notification at points of interest in the life of a job, the submitting user, or other designated users, can track the progress of a batch job.

The **–N** option allows users to associate a name with the batch job. The job name in no way affects the processing of the batch job, but rather serves as a mnemonic handle for users. For example, the batch job name can help the user distinguish between multiple jobs listed by the *qstat* utility.

The **–o** option allows users to redirect the standard output stream. A user might, for example, wish to redirect to the null device the standard output stream of a job that produces copious yet superfluous output.

The **–P** option allows users to designate the relative priority of a batch job for selection from a queue.

The **–q** option allows users to specify an initial queue for the batch job. If the user specifies a routing queue, the batch batch server routes the batch job to another queue for execution or further routing. If the user specifies a non-routing queue, the batch server of the queue eventually executes the batch job.

The **–r** option allows users to control whether the submitted job will be rerun if the controlling batch node fails during execution of the batch job. The **–r** option likewise allows users to indicate whether or not the batch job is eligible to be rerun by the *qrerun* utility. Some jobs cannot be correctly rerun because of changes they make in the state of databases or other aspects of their environment. This volume of IEEE Std. 1003.1-200x specifies that the default, if the **–r** option is not presented to the utility, will be that the batch job cannot be rerun, since the result of rerunning a non-rerunable job might be catastrophic.

The **–S** option allows users to specify the program (usually a shell) that will be invoked to process the script of the batch job. This option has been modified to allow a list of shell names and locations associated with different hosts.

The **–u** option is useful when the submitting user is authorized to use more than one account on a given host, in which case the **–u** option allows the user to select from among those accounts. The option-argument is a list of user-host pairs, so that the submitting user can provide different user identifiers for different nodes in the event the batch job is routed. The **–u** option provides a lot of flexibility to accommodate sites with complex account structures. Users that have the same user identifier on all the hosts they are authorized to use will not need to use the **–u** option.

The **–V** option allows users to export all their current environment variables, as of the time the batch job is submitted, to the context of the processes of the batch job.

The **–v** option allows users to export specific environment variables from their current process to the processes of the batch job.

The **–z** option allows users to suppress the writing of the batch job identifier to standard output. The **–z** option is an existing NQS practice that has been standardized.

Historically, the *qsub* utility has served the batch job-submission function in the NQS system, the existing practice on which it is based. Some changes and additions have been made to the *qsub* utility in this volume of IEEE Std. 1003.1-200x, *vis-a-vis* NQS, as a result of the growing pool of experience with distributed batch systems.

The set of features of the *qsub* utility as defined in this volume of IEEE Std. 1003.1-200x appears to incorporate all the common existing practice on potentially POSIX-conformant platforms. Where implementors wish to extend the functionality of their *qsub* utility, they may (as defined

by IEEE Std. 1003.1-200x) use the **–W** option to provide implementation-defined extensions.

FUTURE DIRECTIONS

None.

qrerun, *qstat*, *touch*, Chapter 3 (on page 2313)

CHANGE HISTORY

Derived from IEEE Std. 1003.2d-1994.

Issue 6

The **–l** option has been removed as there is no portable description of the resources that are allowed or required by the batch job.

NAME

read — read a line from standard input

SYNOPSIS

```
read [–r] var...
```

DESCRIPTION

The *read* utility shall read a single line from standard input.

By default, unless the **–r** option is specified, backslash (`'\'`) shall act as an escape character, as described in Section 2.2.1 (on page 2236). If standard input is a terminal device and the invoking shell is interactive, *read* shall prompt for a continuation line when:

- The shell reads an input line ending with a backslash, unless the **–r** option is specified.
- A here-document is not terminated after a <newline> character is entered.

The line shall be split into fields as in the shell (see Section 2.6.5 (on page 2249)); the first field shall be assigned to the first variable *var*, the second field to the second variable *var*, and so on. If there are fewer *var* operands specified than there are fields, the leftover fields and their intervening separators shall be assigned to the last *var*. If there are fewer fields than *var*s, the remaining *var*s shall be set to empty strings.

The setting of variables specified by the *var* operands shall affect the current shell execution environment; see Section 2.13 (on page 2273). If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . –exec read ... \;
```

it shall not affect the shell variables in the caller's environment.

OPTIONS

The *read* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option is supported:

–r Do not treat a backslash character in any special way. Consider each backslash to be part of the input line.

OPERANDS

The following operand shall be supported:

var The name of an existing or nonexisting shell variable.

STDIN

The standard input shall be a text file.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *read*:

IFS Determine the internal field separators used to delimit fields; see Section 2.5.3 (on page 2242).

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables

31523 contains an invalid setting, the utility shall behave as if none of the variables had
31524 been defined.

31525 *LC_ALL* If set to a non-empty string value, override the values of all the other
31526 internationalization variables.

31527 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
31528 characters (for example, single-byte as opposed to multi-byte characters in
31529 arguments).

31530 *LC_MESSAGES*
31531 Determine the locale that should be used to affect the format and contents of
31532 diagnostic messages written to standard error.

31533 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

31534 *PS2* Provide the prompt string that an interactive shell shall write to standard error
31535 when a line ending with a backslash is read and the **–r** option was not specified, or
31536 if a here-document is not terminated after a <newline> character is entered.

31537 **ASYNCHRONOUS EVENTS**
31538 Default.

31539 **STDOUT**
31540 Not used.

31541 **STDERR**
31542 Used for diagnostic messages and prompts for continued input.

31543 **OUTPUT FILES**
31544 None.

31545 **EXTENDED DESCRIPTION**
31546 None.

31547 **EXIT STATUS**
31548 The following exit values shall be returned:

31549 0 Successful completion.

31550 >0 End-of-file was detected or an error occurred.

31551 **CONSEQUENCES OF ERRORS**
31552 Default.

31553 **APPLICATION USAGE**
31554 The *read* utility has historically been a shell built-in.

31555 The **–r** option is included to enable *read* to subsume the purpose of the *line* utility, which is not
31556 included in IEEE Std. 1003.1-200x.

31557 The results are undefined if an end-of-file is detected following a backslash at the end of a line
31558 when **–r** is not specified.

31559 **EXAMPLES**
31560 The following command:

```
31561 while read –r xx yy
31562 do
31563     printf "%s %s\n" "$yy" "$xx"
31564 done < input_file
```

prints a file with the first field of each line moved to the end of the line.

RATIONALE

The *read* utility historically has been a shell built-in. It was separated off into its own utility to take advantage of the richer description of functionality introduced by this volume of IEEE Std. 1003.1-200x.

Since *read* affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . –exec read ... \;
```

it does not affect the shell variables in the environment of the caller.

FUTURE DIRECTIONS

None.

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Relocated from the *sh* description for alignment with the ISO / IEC 9945-2: 1993 standard.

NAME

renice — set nice values of running processes

SYNOPSIS

UP

```
renice –n increment [–g | –p | –u] ID ...
```

DESCRIPTION

The *renice* utility shall request that the nice values (see the Base Definitions volume of IEEE Std. 1003.1-200x, Section 3.241, Nice Value) of one or more running processes be changed. By default, the applicable processes are specified by their process IDs. When a process group is specified (see **–g**), the request applies to all processes in the process group.

The nice value shall be bounded in an implementation-defined manner. If the requested *increment* would raise or lower the nice value of the executed utility beyond implementation-defined limits, then the limit whose value was exceeded shall be used.

When a user is *renice*d, the request applies to all processes whose saved set-user-ID matches the user ID corresponding to the user.

Regardless of which options are supplied or any other factor, *renice* shall not alter the nice values of any process unless the user requesting such a change has appropriate privileges to do so for the specified process. If the user lacks appropriate privileges to perform the requested action, the utility shall return an error status.

The saved set-user-ID of the user's process shall be checked instead of its effective user ID when *renice* attempts to determine the user ID of the process in order to determine whether the user has appropriate privileges.

OPTIONS

The *renice* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–g Interpret all operands as unsigned decimal integer process group IDs.

–n *increment* Specify how the nice value of the specified process or processes is to be adjusted. The *increment* option-argument is a positive or negative decimal integer that shall be used to modify the nice value of the specified process or processes.

Positive *increment* values shall cause a lower nice value. Negative *increment* values may require appropriate privileges and shall cause a higher nice value.

–p Interpret all operands as unsigned decimal integer process IDs. The **–p** option is the default if no options are specified.

–u Interpret all operands as users. If a user exists with a user name equal to the operand, then the user ID of that user is used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it shall be used as the numeric user ID of the user.

OPERANDS

The following operands shall be supported:

ID A process ID, process group ID, or user name/user ID, depending on the option selected.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *renice*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. Adjust the nice value so that process IDs 987 and 32 would have a lower nice value:

   ```
   renice –n 5 –p 987 32
   ```

2. Adjust the nice value so that group IDs 324 and 76 would have a higher nice value, if the user has the appropriate privileges to do so:

   ```
   renice –n –4 –g 324 76
   ```

3. Adjust the nice value so that numeric user ID 8 and user **sas** would have a lower nice value:

   ```
   renice –n 4 –u 8 sas
   ```

Useful nice value increments on historical systems include 19 or 20 (the affected processes run only when nothing else in the system attempts to run) and any negative number (to make processes run faster).

RATIONALE

The *gid*, *pid*, and *user* specifications do not fit either the definition of operand or option-argument. However, for clarity, they have been included in the OPTIONS section, rather than the OPERANDS section.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in POSIX.4 make the notion of a single underlying priority for all scheduling policies problematic. Some systems may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std. 1003.1-200x, and others may have no effect at all. Because of the use of ''implementation-defined'' in *nice* and *renice*, a wide range of implementation strategies are possible.

Originally, this utility was written in the historical manner, using the term ''nice value''. This was always a point of concern with users because it was never intuitively obvious what this meant. With a newer version of *renice*, which used the term ''system scheduling priority'', it was hoped that novice users could better understand what this utility was meant to do. Also, it would be easier to document what the utility was meant to do. Unfortunately, the addition of the POSIX realtime scheduling capabilities introduced the concepts of process and thread scheduling priorities that were totally unaffected by the *nice*/*renice* utilities or the *nice*( )/*setpriority*( ) functions. Continuing to use the term ''system scheduling priority'' would have incorrectly suggested that these utilities and functions were indeed affecting these realtime priorities. It was decided to revert to the historical term ''nice value'' to reference this unrelated process attribute.

Although this utility has use by system administrators (and in fact appears in the system administration portion of the BSD documentation), the standard developers considered that it was very useful for individual end users to control their own processes.

FUTURE DIRECTIONS

None.

nice

CHANGE HISTORY

First released in Issue 4.

Issue 5

In the SYNOPSIS, an ellipsis is added to the **–u** option in all three obsolescent forms.

Issue 6

This utility is now marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent forms of the SYNOPSIS are removed.

Text previously conditional on POSIX_SAVED_IDS is mandatory in this issue. This is a FIPS requirement.

NAME

rm — remove directory entries

SYNOPSIS

```
rm [–fiRr] file...
```

DESCRIPTION

The *rm* utility shall remove the directory entry specified by each *file* argument.

If either of the files dot or dot-dot are specified as the basename portion of an operand (that is, the final path name component), *rm* shall write a diagnostic message to standard error and do nothing more with such operands.

For each *file* the following steps shall be taken:

1. If the *file* does not exist:
   a. If the **–f** option is not specified, write a diagnostic message to standard error.
   b. Go on to any remaining *files*.
2. If *file* is of type directory, the following steps shall be taken:
   a. If neither the **–R** option nor the **–r** option is specified, write a diagnostic message to standard error, do nothing more with *file*, and go on to any remaining files.
   b. If the **–f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **–i** option is specified, write a prompt to standard error and read a line from the standard input. If the response is not affirmative, do nothing more with the current file and go on to any remaining files.
   c. For each entry contained in *file*, other than dot or dot-dot, the four steps listed here (1-4) shall be taken with the entry as if it were a *file* operand. The *rm* utility shall not traverse directories by following symbolic links into other parts of the hierarchy, but shall remove the links themselves.
   d. If the **–i** option is specified, write a prompt to standard error and read a line from the standard input. If the response is not affirmative, do nothing more with the current file, and go on to any remaining files.
3. If *file* is not of type directory, the **–f** option is not specified, and either the permissions of *file* do not permit writing and the standard input is a terminal or the **–i** option is specified, write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, do nothing more with the current file and go on to any remaining files.
4. If the current file is a directory, *rm* shall perform actions equivalent to the *rmdir*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x called with a path name of the current file used as the *path* argument. If the current file is not a directory, *rm* shall perform actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x called with a path name of the current file used as the *path* argument.

   If this fails for any reason, *rm* shall write a diagnostic message to standard error, do nothing more with the current file, and go on to any remaining files.

The *rm* utility shall be able to descend to arbitrary depths in a file hierarchy, and shall not fail due to path length limitations (unless an operand specified by the user exceeds system limitations).

OPTIONS

The *rm* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

–f Do not prompt for confirmation. Do not write diagnostic messages or modify the exit status in the case of nonexistent operands. Any previous occurrences of the **–i** option shall be ignored.

–i Prompt for confirmation as described previously. Any previous occurrences of the **–f** option shall be ignored.

–R Remove file hierarchies. See the DESCRIPTION.

–r Equivalent to **–R**.

OPERANDS

The following operand shall be supported:

file A path name of a directory entry to be removed.

STDIN

Used to read an input line in response to each prompt specified in the STDOUT section. Otherwise, the standard input shall not be used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rm*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

31803 **ASYNCHRONOUS EVENTS**
31804 Default.

31805 **STDOUT**
31806 Not used.

31807 **STDERR**
31808 Prompts shall be written to standard error under the conditions specified in the DESCRIPTION
31809 and OPTIONS sections. The prompts shall contain the *file* path name, but their format is
31810 otherwise unspecified. The standard error also shall be used for diagnostic messages.

31811 **OUTPUT FILES**
31812 None.

31813 **EXTENDED DESCRIPTION**
31814 None.

31815 **EXIT STATUS**
31816 The following exit values shall be returned:

31817 0 All of the named directory entries for which *rm* performed actions equivalent to *rmdir*( ) or
31818 *unlink*( ) functions were removed.

31819 >0 An error occurred.

31820 **CONSEQUENCES OF ERRORS**
31821 Default.

31822 **APPLICATION USAGE**
31823 The *rm* utility is forbidden to remove the names dot and dot-dot in order to avoid the
31824 consequences of inadvertently doing something like:

31825 `rm –r .*`

31826 Some systems do not permit the removal of the last link to an executable binary file that is being
31827 executed; see the [EBUSY] error in the *unlink*( ) function defined in the System Interfaces volume
31828 of IEEE Std. 1003.1-200x. Thus, the *rm* utility can fail to remove such files.

31829 The **–i** option causes *rm* to prompt and read the standard input even if the standard input is not
31830 a terminal, but in the absence of **–i** the mode prompting is not done when the standard input is
31831 not a terminal.

31832 **EXAMPLES**

31833 1. The following command:

31834 `rm a.out core`

31835 removes the directory entries: **a.out** and **core**.

31836 2. The following command:

31837 `rm –Rf junk`

31838 removes the directory **junk** and all its contents, without prompting.

31839 **RATIONALE**
31840 The **–i** option causes *rm* to prompt and read the standard input even if the standard input is not
31841 a terminal, but, in the absence of **–i**, the mode prompting is not done when the standard input is
31842 not a terminal.

31843 For absolute clarity, paragraphs (2b) and (3) in the DESCRIPTION of *rm* describing the behavior
31844 when prompting for confirmation, should be interpreted in the following manner:

```
if ((NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the **–f** option, or using the **–i** option, relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The **–r** option is historical practice on all known systems. The synonym **–R** option is provided for consistency with the other utilities in this volume of IEEE Std. 1003.1-200x that provide options requesting recursive descent through the file hierarchy.

The behavior of the **–f** option in historical versions of *rm* is inconsistent. In general, along with ''forcing'' the unlink without prompting for permission, it always causes diagnostic messages to be suppressed and the exit status to be unmodified for nonexistent operands and files that cannot be unlinked. In some versions, however, the **–f** option suppresses usage messages and system errors as well. Suppressing such messages is not a service to either shell scripts or users.

It is less clear that error messages regarding files that cannot be unlinked (removed) should be suppressed. Although this is historical practice, this volume of IEEE Std. 1003.1-200x does not permit the **–f** option to suppress such messages.

When given the **–r** and **–i** options, historical versions of *rm* prompt the user twice for each directory, once before removing its contents and once before actually attempting to delete the directory entry that names it. This allows the user to ''prune'' the file hierarchy walk. Historical versions of *rm* were inconsistent in that some did not do the former prompt for directories named on the command line and others had obscure prompting behavior when the **–i** option was specified and the permissions of the file did not permit writing. The POSIX Shell and Utilities *rm* differs little from historic practice, but does require that prompts be consistent. Historical versions of *rm* were also inconsistent in that prompts were done to both standard output and standard error. This volume of IEEE Std. 1003.1-200x requires that prompts be done to standard error, for consistency with *cp* and *mv*, and to allow historical extensions to *rm* that provide an option to list deleted files on standard output.

The *rm* utility is required to descend to arbitrary depths so that any file hierarchy may be deleted. This means, for example, that the *rm* utility cannot run out of file descriptors during its descent (that is, if the number of file descriptors is limited, *rm* cannot be implemented in the historical fashion where one file descriptor is used per directory level). Also, *rm* is not permitted to fail because of path length restrictions, unless an operand specified by the user is longer than {PATH_MAX}.

The *rm* utility removes symbolic links themselves, not the files they refer to, as a consequence of the dependence on the *unlink*( ) functionality, per the DESCRIPTION. When removing hierarchies with **–r** or **–R**, the prohibition on following symbolic links has to be made explicit.

FUTURE DIRECTIONS

None.

Issue 6

Text is added to clarify actions relating to symbolic links as specified in the IEEE P1003.2b draft standard.

NAME

rmdel — remove a delta from an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI
```
rmdel –r SID file...
```

DESCRIPTION

The *rmdel* utility shall remove the delta specified by the SID from each named SCCS file. The delta to be removed shall be the most recent delta in its branch in the delta chain of each named SCCS file. In addition, the application shall ensure that the SID specified is not that of a version being edited for the purpose of making a delta; that is, if a *p-file* (see *get* (on page 2685)) exists for the named SCCS file, the SID specified shall not appear in any entry of the *p-file*.

Removal of a delta shall be restricted to:

1. The user who made the delta
2. The owner of the SCCS file
3. The owner of the directory containing the SCCS file

OPTIONS

The *rmdel* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:

–r *SID* Specify the SCCS identification string (*SID*) of the delta to be deleted.

OPERANDS

The following operand shall be supported:

file A path name of an existing SCCS file or a directory. If *file* is a directory, the *rmdel* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the path name does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is '–', the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only when the *file* operand is specified as '–'. Each line of the text file shall be interpreted as an SCCS path name.

INPUT FILES

The SCCS files are files of unspecified format.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *rmdel*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
Used only for diagnostic messages.

OUTPUT FILES
The SCCS files are files of unspecified format. During processing of a *file*, a temporary *x-file*, as described in *admin* (on page 2340), may be created and deleted; a locking *z-file*, as described in *get* (on page 2685), may be created and deleted.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements. |

The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements. |

31983 **NAME**

31984 rmdir — remove directories

31985 **SYNOPSIS**

31986 `rmdir [–p] dir...`

31987 **DESCRIPTION**

31988 The *rmdir* utility shall remove the directory entry specified by each *dir* operand, which, in order
31989 to succeed, the application shall ensure refers to an empty directory.

31990 Directories shall be processed in the order specified. If a directory and a subdirectory of that
31991 directory are specified in a single invocation of the *rmdir* utility, the application shall specify the
31992 subdirectory before the parent directory so that the parent directory will be empty when the
31993 *rmdir* utility tries to remove it.

31994 **OPTIONS**

31995 The *rmdir* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
31996 12.2, Utility Syntax Guidelines.

31997 The following option shall be supported:

31998 **–p** Remove all directories in a path name. For each *dir* operand:

31999 1. The directory entry it names shall be removed.

32000 2. If the *dir* operand includes more than one path name component, effects
32001 equivalent to the following command shall occur:

32002 `rmdir –p $(dirname dir)`

32003 **OPERANDS**

32004 The following operand shall be supported:

32005 *dir* A path name of an empty directory to be removed.

32006 **STDIN**

32007 Not used.

32008 **INPUT FILES**

32009 None.

32010 **ENVIRONMENT VARIABLES**

32011 The following environment variables shall affect the execution of *rmdir*:

32012 *LANG* Provide a default value for the internationalization variables that are unset or null.
32013 If *LANG* is unset or null, the corresponding value from the implementation-
32014 defined default locale shall be used. If any of the internationalization variables
32015 contains an invalid setting, the utility shall behave as if none of the variables had
32016 been defined.

32017 *LC_ALL* If set to a non-empty string value, override the values of all the other
32018 internationalization variables.

32019 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
32020 characters (for example, single-byte as opposed to multi-byte characters in
32021 arguments).

32022 *LC_MESSAGES*

32023 Determine the locale that should be used to affect the format and contents of
32024 diagnostic messages written to standard error.

32025 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

32026 **ASYNCHRONOUS EVENTS**
32027 Default.

32028 **STDOUT**
32029 Not used.

32030 **STDERR**
32031 Used only for diagnostic messages.

32032 **OUTPUT FILES**
32033 None.

32034 **EXTENDED DESCRIPTION**
32035 None.

32036 **EXIT STATUS**
32037 The following exit values shall be returned:

32038 0 Each directory entry specified by a *dir* operand was removed successfully.

32039 >0 An error occurred.

32040 **CONSEQUENCES OF ERRORS**
32041 Default.

32042 **APPLICATION USAGE**
32043 The definition of an empty directory is one that contains, at most, directory entries for dot and
32044 dot-dot.

32045 **EXAMPLES**
32046 If a directory **a** in the current directory is empty except it contains a directory **b** and **a/b** is empty
32047 except it contains a directory **c**:

32048
```
rmdir –p a/b/c
```

32049 removes all three directories.

32050 **RATIONALE**
32051 On historical System V systems, the **–p** option also caused a message to be written to the
32052 standard output. The message indicated whether the whole path was removed or whether part
32053 of the path remained for some reason. The STDERR section requires this diagnostic when the
32054 entire path specified by a *dir* operand is not removed, but does not allow the status message
32055 reporting success to be written as a diagnostic.

32056 The *rmdir* utility on System V also included an **–s** option that suppressed the informational
32057 message output by the **–p** option. This option has been omitted because the informational
32058 message is not specified by this volume of IEEE Std. 1003.1-200x.

32059 **FUTURE DIRECTIONS**
32060 None.

32061 **SEE ALSO**
32062 *rm*, the System Interfaces volume of IEEE Std. 1003.1-200x, *remove*( ), *rmdir*( ), *unlink*( )

32063 **CHANGE HISTORY**
32064 First released in Issue 2.

Issue 4

Separated from the *rm* description and aligned with the ISO/IEC 9945-2:1993 standard.

Issue 6

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

32069 **NAME**

32070 sact — print current SCCS file-editing activity (**DEVELOPMENT**)

32071 **SYNOPSIS**

32072 XSI
```
sact file...
```
32073

32074 **DESCRIPTION**

32075 The *sact* utility shall inform the user of any impending deltas to a named SCCS file by writing a
32076 list to standard output. This situation occurs when *get* **−e** has been executed previously without
32077 a subsequent execution of *delta*.

32078 **OPTIONS**

32079 None.

32080 **OPERANDS**

32081 The following operand shall be supported:

32082 *file* A path name of an existing SCCS file or a directory. If *file* is a directory, the *sact* |
32083 utility shall behave as though each file in the directory were specified as a named |
32084 file, except that non-SCCS files (last component of the path name does not begin |
32085 with **s.**) and unreadable files shall be silently ignored. |

32086 If a single instance *file* is specified as '−', the standard input shall be read; each |
32087 line of the standard input shall be taken to be the name of an SCCS file to be |
32088 processed. Non-SCCS files and unreadable files shall be silently ignored. |

32089 **STDIN**

32090 The standard input shall be a text file used only when the *file* operand is specified as '−'. Each
32091 line of the text file shall be interpreted as an SCCS path name.

32092 **INPUT FILES**

32093 Any SCCS files interrogated are files of an unspecified format.

32094 **ENVIRONMENT VARIABLES**

32095 The following environment variables shall affect the execution of *sact*:

32096 *LANG* Provide a default value for the internationalization variables that are unset or null.
32097 If *LANG* is unset or null, the corresponding value from the implementation- |
32098 defined default locale shall be used. If any of the internationalization variables |
32099 contains an invalid setting, the utility shall behave as if none of the variables had
32100 been defined.

32101 *LC_ALL* If set to a non-empty string value, override the values of all the other
32102 internationalization variables.

32103 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
32104 characters (for example, single-byte as opposed to multi-byte characters in
32105 arguments and input files).

32106 *LC_MESSAGES*
32107 Determine the locale that should be used to affect the format and contents of
32108 diagnostic messages written to standard error.

32109 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

32110 **ASYNCHRONOUS EVENTS**
32111 Default.

32112 **STDOUT**
32113 The output for each named file shall consist of a line in the following format:

32114 `"%sΔ%sΔ%sΔ%sΔ%s\n", <SID>, <new SID>, <login>, <date>, <time>`

32115 <*SID*> Specifies the SID of a delta that currently exists in the SCCS file to which changes
32116 are made to make the new delta.

32117 <*new SID*> Specifies the SID for the new delta to be created.

32118 <*login*> Contains the login name of the user who makes the delta (that is, who executed a
32119 *get* for editing).

32120 <*date*> Contains the date that *get* **–e** was executed, in the format used by the *prs* **:D:** data
32121 keyword.

32122 <*time*> Contains the time that *get* **–e** was executed, in the format used by the *prs* **:T:** data
32123 keyword.

32124 If there is more than one named file or if a directory or standard input is named, each path name
32125 shall be written before each of the preceding lines:

32126 `"\n%s:\n", <pathname>`

32127 **STDERR**
32128 Used only for optional informative messages concerning SCCS files with no impending deltas,
32129 and for diagnostic messages.

32130 **OUTPUT FILES**
32131 None.

32132 **EXTENDED DESCRIPTION**
32133 None.

32134 **EXIT STATUS**
32135 The following exit values shall be returned:

32136 0 Successful completion.

32137 >0 An error occurred.

32138 **CONSEQUENCES OF ERRORS**
32139 Default.

32140 **APPLICATION USAGE**
32141 None.

32142 **EXAMPLES**
32143 None.

32144 **RATIONALE**
32145 None.

32146 **FUTURE DIRECTIONS**
32147 None.

Issue 4, Version 2

The STDERR section encompasses informative messages concerning SCCS files with no impending deltas.

Issue 6

The normative text is reworded to emphasise the term ‘‘shall’’ for implementation requirements.

NAME

sccs — front end for the SCCS subsystem (**DEVELOPMENT**)

SYNOPSIS

XSI
```
sccs [–r][–d path][–p path] command [options...][operands...]
```

DESCRIPTION

The *sccs* utility is a front end to the SCCS programs. It also includes the capability to run set-user-id to another user to provide additional protection.

The *sccs* utility shall invoke the specified *command* with the specified *options* and *operands*. By default, each of the *operands* shall be modified by prefixing it with the string **SCCS/s.**.

The *command* can be the name of one of the SCCS utilities in this volume of IEEE Std. 1003.1-200x (*admin*, *delta*, *get*, *prs*, *rmdel*, *sact*, *unget*, *val*, or *what*) or one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

OPTIONS

The *sccs* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that *options* operands are actually options to be passed to the utility named by *command*. When the portion of the command:

command **[***options ...* **] [***operands ...* **]**

is considered, all of the pseudo-utilities used as *command* shall support the Utility Syntax Guidelines. Any of the other SCCS utilities that can be invoked in this manner support the Guidelines to the extent indicated by their individual OPTIONS sections.

The following options shall be supported preceding the *command* operand:

–d *path* A path name of a directory to be used as a root directory for the SCCS files. The default is the current directory. The **–d** option takes precedence over the *PROJECTDIR* variable. See **–p**.

–p *path* A path name of a directory in which the SCCS files are located. The default is the **SCCS** directory.

The **–p** option differs from the **–d** option in that the **–d** option-argument is prefixed to the entire path name and the **–p** option-argument is inserted before the final component of the path name. For example:

```
sccs –d /x –p y get a/b
```

converts to:

```
get /x/a/y/s.b
```

This allows the creation of aliases such as:

```
alias syssccs="sccs –d /usr/src"
```

which is used as:

```
syssccs get cmd/who.c
```

–r Invoke *command* with the real user ID of the process, not any effective user ID that the *sccs* utility is set to. Certain commands (*admin*, **check**, **clean**, **diffs**, **info**, *rmdel*, and **tell**) cannot be run set-user-ID by all users, since this would allow anyone to change the authorizations. These commands are always run as the real user.

OPERANDS

The following operands shall be supported:

command An SCCS utility name or the name of one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

options An option or option-argument to be passed to *command*.

operands An operand to be passed to *command*.

STDIN

See the utility description for the specified *command*.

INPUT FILES

See the utility description for the specified *command*.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sccs*:

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PROJECTDIR
Provide a default value for the **−d** *path* option. If the value of *PROJECTDIR* begins with a slash, it shall be considered an absolute path name; otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory shall be examined for a subdirectory **src** or **source**. If such a directory is found, it shall be used. Otherwise, the value shall be used as a relative path name.

Additional environment variable effects may be found in the utility description for the specified *command*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the utility description for the specified *command*.

STDERR

See the utility description for the specified *command*.

OUTPUT FILES

See the utility description for the specified *command*.

EXTENDED DESCRIPTION

The following pseudo-utilities shall be supported as *command* operands. All options referred to in the following list are values given in the *options* operands following *command*.

check Equivalent to **info**, except that nothing shall be printed if nothing is being edited, and a non-zero exit status shall be returned if anything is being edited. The intent is to have this included in an ''install'' entry in a makefile to ensure that everything is included into the SCCS file before a version is installed.

clean Remove everything from the current directory that can be recreated from SCCS files, but do not remove any files being edited. If the **–b** option is given, branches shall be ignored in the determination of whether they are being edited; this is dangerous if branches are kept in the same directory.

create Create an SCCS file, taking the initial contents from the file of the same name. Any options to *admin* are accepted. If the creation is successful, the original files shall be renamed by prefixing the basenames with a comma. These renamed files should be removed after it has been verified that the SCCS files have been created successfully.

delget Perform a *delta* on the named files and then *get* new versions. The new versions shall have ID keywords expanded and shall not be editable. Any **–m**, **–p**, **–r**, **–s**, and **–y** options shall be passed to *delta*, and any **–b**, **–c**, **–e**, **–i**, **–k**, **–l**, **–s**, and **–x** options shall be passed to *get*.

deledit Equivalent to **delget**, except that the *get* phase shall include the **–e** option. This option is useful for making a checkpoint of the current editing phase. The same options are passed to *delta* as described above, and all the options listed for *get* above except **–e** are passed to **edit**.

diffs Write a difference listing between the current version of the files checked out for editing and the versions in SCCS format. Any **–r**, **–c**, **–i**, **–x**, and **–t** options shall be passed to *get*; any **–l**, **–s**, **–e**, **–f**, **–h**, and **–b** options shall be passed to *diff*. A **–C** option shall be passed to *diff* as **–c**.

edit Equivalent to *get* **–e**.

fix Remove the named delta, but leave a copy of the delta with the changes that were in it. It is useful for fixing small compiler bugs, and so on. The application shall ensure that it is followed by a **–r** *SID* option. Since **fix** doesn't leave audit trails, it should be used carefully.

info Write a listing of all files being edited. If the **–b** option is given, branches (that is, SIDs with two or fewer components) shall be ignored. If a **–u** *user* option is given, then only files being edited by the named user shall be listed. A **–U** option shall be equivalent to **–u**<*current user*>.

print Write out verbose information about the named files, equivalent to *sccs prs*.

tell Write a <newline>-separated list of the files being edited to standard output. Takes the **–b**, **–u**, and **–U** options like **info** and **check**.

unedit This is the opposite of an **edit** or a *get* **–e**. It should be used with caution, since any changes made since the *get* are lost.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Many of the SCCS utilities take directory names as operands as well as specific file names. The pseudo-utilities supported by *sccs* are not described as having this capability, but are not prohibited from doing so.

EXAMPLES

1. To get a file for editing, edit it and produce a new delta:

```
sccs get –e file.c
ex file.c
sccs delta file.c
```

2. To get a file from another directory:

```
sccs –p /usr/src/sccs/s. get cc.c
```

or:

```
sccs get /usr/src/sccs/s.cc.c
```

3. To make a delta of a large number of files in the current directory:

```
sccs delta *.c
```

4. To get a list of files being edited that are not on branches:

```
sccs info –b
```

5. To delta everything being edited by the current user:

```
sccs delta $(sccs tell –U)
```

6. In a makefile, to get source files from an SCCS file if it does not already exist:

```
SRCS = <list of source files>
$(SRCS):
    sccs get $(REL) $@
```

RATIONALE

SCCS and its associated utilities are part of the XSI Development Utilities option within the XSI extension.

SCCS is an abbreviation for Source Code Control System. It is a maintenance and enhancement tracking tool. When a file is put under SCCS, the source code control system maintains the file and, when changes are made, identifies and stores them in the file with the original source code and/or documentation. As other changes are made, they too are identified and retained in the file.

Retrieval of the original and any set of changes is possible. Any version of the file as it develops can be reconstructed for inspection or additional modification. History data can be stored with each version, documenting why the changes were made, who made them, and when they were made.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from ''otherwise, the home directory of a user of that name is examined'' to ''otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory is examined''.

The normative text is reworded to avoid use of the term ''must'' for application requirements.

The normative text is reworded to emphasise the term ''shall'' for implementation requirements.

32338 **NAME**

32339 sed — stream editor

32340 **SYNOPSIS**

32341 `sed [-n] script[file...]`

32342 `sed [-n][-e script]...[-f script_file]...[file...]`

32343 **DESCRIPTION**

32344 The *sed* utility is a stream editor that shall read one or more text files, make editing changes
32345 according to a script of editing commands, and write the results to standard output. The script
32346 shall be obtained from either the *script* operand string or a combination of the option-arguments
32347 from the **–e** *script* and **–f** *script_file* options.

32348 **OPTIONS**

32349 The *sed* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section
32350 12.2, Utility Syntax Guidelines, except that the order of presentation of the **–e** and **–f** options is
32351 significant.

32352 The following options shall be supported:

32353 **–e** *script* Add the editing commands specified by the *script* option-argument to the end of
32354 the script of editing commands. The *script* option-argument shall have the same
32355 properties as the *script* operand, described in the OPERANDS section.

32356 **–f** *script_file* Add the editing commands in the file *script_file* to the end of the script.

32357 **–n** Suppress the default output (in which each line, after it is examined for editing, is
32358 written to standard output). Only lines explicitly selected for output are written.

32359 Multiple **–e** and **–f** options may be specified. All commands shall be added to the script in the
32360 order specified, regardless of their origin.

32361 **OPERANDS**

32362 The following operands shall be supported:

32363 *file* A path name of a file whose contents are read and edited. If multiple *file* operands
32364 are specified, the named files shall be read in the order specified and the
32365 concatenation shall be edited. If no *file* operands are specified, the standard input
32366 shall be used.

32367 *script* A string to be used as the script of editing commands. The application shall not
32368 present a *script* that violates the restrictions of a text file except that the final
32369 character need not be a <newline> character.

32370 **STDIN**

32371 The standard input shall be used only if no *file* operands are specified. See the INPUT FILES
32372 section.

32373 **INPUT FILES**

32374 The input files shall be text files. The *script_file*s named by the **–f** option shall consist of editing
32375 commands.

32376 **ENVIRONMENT VARIABLES**

32377 The following environment variables shall affect the execution of *sed*:

32378 *LANG* Provide a default value for the internationalization variables that are unset or null.
32379 If *LANG* is unset or null, the corresponding value from the implementation-
32380 defined default locale shall be used. If any of the internationalization variables
32381 contains an invalid setting, the utility shall behave as if none of the variables had

32382 been defined.

32383 *LC_ALL* If set to a non-empty string value, override the values of all the other
32384 internationalization variables.

32385 *LC_COLLATE*
32386 Determine the locale for the behavior of ranges, equivalence classes, and multi-
32387 character collating elements within regular expressions.

32388 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
32389 characters (for example, single-byte as opposed to multi-byte characters in
32390 arguments and input files), and the behavior of character classes within regular
32391 expressions.

32392 *LC_MESSAGES*
32393 Determine the locale that should be used to affect the format and contents of
32394 diagnostic messages written to standard error.

32395 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

32396 **ASYNCHRONOUS EVENTS**
32397 Default.

32398 **STDOUT**
32399 The input files shall be written to standard output, with the editing commands specified in the
32400 script applied. If the **–n** option is specified, only those input lines selected by the script shall be
32401 written to standard output.

32402 **STDERR**
32403 Used only for diagnostic messages.

32404 **OUTPUT FILES**
32405 The output files shall be text files whose formats are dependent on the editing commands given.

32406 **EXTENDED DESCRIPTION**
32407 The *script* shall consist of editing commands of the following form:

32408 **[***address***[,***address***]]***function*

32409 where *function* represents a single-character command verb from the list in **Editing Commands**
32410 **in sed** (on page 3053), followed by any applicable arguments.

32411 Zero or more <blank> characters shall be accepted before the first address and before function.
32412 Any number of semicolons shall be accepted before the first address.

32413 In default operation, *sed* cyclically shall copy a line of input, less its terminating <newline>, into
32414 a pattern space (unless there is something left after a **D** command), apply in sequence all
32415 commands whose addresses select that pattern space, and at the end of the script copy the
32416 pattern space to standard output (except when **–n** is specified) and delete the pattern space.
32417 Whenever the pattern space is written to standard output or a named file, *sed* shall immediately
32418 follow it with a <newline>.

32419 Some of the editing commands use a hold space to save all or part of the pattern space for
32420 subsequent retrieval. The pattern and hold spaces shall each be able to hold at least 8 192 bytes.

Addresses in sed

An address is either a decimal number that counts input lines cumulatively across files, a `'$'` character that addresses the last line of input, or a context address (which consists of a BRE, as described in **Regular Expressions in sed**, preceded and followed by a delimiter, usually a slash).

An editing command with no addresses shall select every pattern space.

An editing command with one address shall select each pattern space that matches the address.

An editing command with two addresses shall select the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line shall be selected.) Starting at the first line following the selected range, *sed* shall look again for the first address. Thereafter, the process shall be repeated. Omitting either or both of the address components in the following form produces undefined results:

[*address***[,***address***]]**

Regular Expressions in sed

The *sed* utility shall support the BREs described in the Base Definitions volume of IEEE Std. 1003.1-200x, Section 9.3, Basic Regular Expressions, with the following additions:

- In a context address, the construction `"\cBREc"`, where *c* is any character other than backslash or <newline>, shall be identical to `"/BRE/"`. If the character designated by *c* appears following a backslash, then it shall be considered to be that literal character, which shall not terminate the BRE. For example, in the context address `"\xabc\xdefx"`, the second *x* stands for itself, so that the BRE is `"abcxdef"`.
- The escape sequence `'\n'` shall match a <newline> embedded in the pattern space. A literal <newline> character shall not be used in the BRE of a context address or in the substitute function.
- If an RE is empty (that is, no pattern is specified) *sed* shall behave as if the last RE used in the last command applied (either as an address or as part of a substitute command) was specified.

Editing Commands in sed

In the following list of editing commands, the maximum number of permissible addresses for each function is indicated by [*0addr*], [*1addr*], or [*2addr*], representing zero, one, or two addresses.

The argument *text* shall consist of one or more lines. Each embedded <newline> in the text shall be preceded by a backslash. Other backslashes in text shall be removed, and the following character shall be treated literally.

The **r** and **w** command verbs, and the *w* flag to the **s** command, take an optional *rfile* (or *wfile*) parameter, separated from the command verb letter or flag by one or more <blank> characters; implementations may allow zero separation as an extension.

The argument *rfile* or the argument *wfile* shall terminate the editing command. Each *wfile* shall be created before processing begins. Implementations shall support at least ten *wfile* arguments in the script; the actual number (greater than or equal to 10) that shall be supported by the implementation is unspecified. The use of the *wfile* parameter shall cause that file to be initially created, if it does not exist, or shall replace the contents of an existing file.

The **b**, **r**, **s**, **t**, **w**, **y**, and **:** command verbs shall accept additional arguments. The following synopses indicate which arguments shall be separated from the command verbs by a single <space>.

The **a** and **r** commands schedule text for later output. The text specified for the **a** command, and the contents of the file specified for the **r** command, shall be written to standard output just before the next attempt to fetch a line of input when executing the **N** or **n** commands, or when reaching the end of the script. If written when reaching the end of the script, and the **–n** option was not specified, the text shall be written after copying the pattern space to standard output. The contents of the file specified for the **r** command shall be as of the time the output is written, not the time the **r** command is applied. The text shall be output in the order in which the **a** and **r** commands were applied to the input.

Command verbs other than **{**, **a**, **b**, **c**, **i**, **r**, **t**, **w**, **:**, and **#** can be followed by a semicolon, optional <blank> characters, and another command verb. However, when the **s** command verb is used with the *w* flag, following it with another command in this manner produces undefined results.

A function can be preceded by one or more '**!**' characters, in which case the function shall be applied if the addresses do not select the pattern space. Zero or more <blank> characters shall be accepted before the first '**!**' character. It is unspecified whether <blank> characters can follow a '**!**' character, and conforming applications shall not follow a '**!**' character with <blank> characters.

[*2addr***] {***function*
function
...
}
Execute a list of *sed* functions only when the pattern space is selected. The list of *sed* functions shall be surrounded by braces and separated by <newline>s, as follows. The braces can be preceded or followed by <blank> characters. The functions can be preceded by <blank> characters, but shall not be followed by <blank> characters. The <right-brace> shall be preceded by a <newline> and can be preceded or followed by <blank> characters.

[*1addr***]a**
text
Write text to standard output as described previously.

[*2addr***]b [***label***]**
Branch to the **:** function bearing the *label*. If *label* is not specified, branch to the end of the script. The implementation shall support *label*s recognized as unique up to at least 8 characters; the actual length (greater than or equal to 8) that shall be supported by the implementation is unspecified. It is unspecified whether exceeding a label length causes an error or a silent truncation.

[*2addr***]c**
text
Delete the pattern space. With a 0 or 1 address or at the end of a 2-address range, place *text* on the output and start the next cycle.

[*2addr***]d**
Delete the pattern space and start the next cycle.

[*2addr***]D**
Delete the initial segment of the pattern space through the first <newline> and start the next cycle.

[*2addr***]g**
Replace the contents of the pattern space by the contents of the hold space.

[*2addr***]G**
Append to the pattern space a <newline> followed by the contents of the hold space.

[*2addr***]h** Replace the contents of the hold space with the contents of the pattern space.

[*2addr***]H** Append to the hold space a <newline> followed by the contents of the pattern space.

[*1addr***]i**
text Write *text* to standard output.

[*2addr***]l** (The letter ell.) Write the pattern space to standard output in a visually unambiguous form. The characters listed in the Base Definitions volume of IEEE Std. 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not applicable. Non-printable characters not in that table shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than 9 bits, the format used for non-printable characters is implementation-defined.

Long lines shall be folded, with the point of folding indicated by writing a backslash followed by a <newline>; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a `'$'`.

[*2addr***]n** Write the pattern space to standard output if the default output has not been suppressed, and replace the pattern space with the next line of input.

If no next line of input is available, the **n** command verb shall branch to the end of the script and quit without starting a new cycle.

[*2addr***]N** Append the next line of input to the pattern space, using an embedded <newline> character to separate the appended material from the original material. Note that the current line number changes.

If no next line of input is available, the **N** command verb shall branch to the end of the script and quit without starting a new cycle or copying the pattern space to standard output.

[*2addr***]p** Write the pattern space to standard output.

[*2addr***]P** Write the pattern space, up to the first <newline>, to standard output.

[*1addr***]q** Branch to the end of the script and quit without starting a new cycle.

[*1addr***]r** *rfile* Copy the contents of *rfile* to standard output as described previously. If *rfile* does not exist or cannot be read, it shall be treated as if it were an empty file, causing no error condition.

[*2addr***]s/***BRE/replacement/flags*
Substitute the replacement string for instances of the BRE in the pattern space. Any character other than backslash or <newline> can be used instead of a slash to delimit the BRE and the replacement. Within the BRE and the replacement, the BRE delimiter itself can be used as a literal character if it is preceded by a backslash.

An ampersand (`'&'`) appearing in the replacement shall be replaced by the string matching the BRE. The special meaning of `'&'` in this context can be suppressed by preceding it by a backslash. The characters "`\`*n*", *where* *n* *is a digit, shall be replaced by the text matched by the corresponding backreference expression. For each backslash* (`'\'`)

32553 *encountered in scanning replacement from beginning to end, the*
32554 *backslash shall be discarded and the following character*
32555 *shall lose its special meaning (if any). It is unspecified*
32556 *what special meaning is given to any character other than*
32557 *'&', '\', or digits.*

32558 *A line can be split by substituting a <newline> character*
32559 *into it. The application shall escape the <newline> in the*
32560 *replacement by preceding it by a backslash. A substitution*
32561 *shall be considered to have been performed even if the*
32562 *replacement string is identical to the string that it*
32563 *replaces. Any backslash used to alter the default meaning of*
32564 *a subsequent character shall be discarded from the BRE or the*
32565 *replacement before evaluating the BRE or using the*
32566 *replacement.*

32567 *The value of flags shall be zero or more of:*

32568 *n* Substitute for the *n*th occurrence only of the BRE found within the |
32569 pattern space.

32570 **g** Globally substitute for all non-overlapping instances of the BRE
32571 rather than just the first one. If both **g** and **n** are specified, the results
32572 are unspecified.

32573 **p** Write the pattern space to standard output if a replacement was
32574 made.

32575 **w** *wfile* Write. Append the pattern space to *wfile* if a replacement was made.
32576 A conforming application shall precede the *wfile* argument with one
32577 or more <blank> characters. If the *w* flag is not the last flag value |
32578 given in a concatenation of multiple flag values, the results are
32579 undefined.

32580 **[***2addr***]t [***label***]**
32581 Test. Branch to the **:** command verb bearing the *label* if any substitutions have been
32582 made since the most recent reading of an input line or execution of a **t**. If *label* is
32583 not specified, branch to the end of the script.

32584 **[***2addr***]w** *wfile*
32585 Append (write) the pattern space to *wfile*. |

32586 **[***2addr***]x** Exchange the contents of the pattern and hold spaces.

32587 **[***2addr***]y/***string1***/***string2***/**
32588 Replace all occurrences of characters in *string1* with the corresponding characters
32589 in *string2*. If a backslash followed by an 'n' appear in *string1* or *string2*, the two |
32590 characters shall be handled as a single <newline> character. If the number of
32591 characters in *string1* and *string2* are not equal, or if any of the characters in *string1*
32592 appear more than once, the results are undefined. Any character other than
32593 backslash or <newline> can be used instead of slash to delimit the strings. If the
32594 delimiter is not *n*, within *string1* and *string2*, the delimiter itself can be used as a
32595 literal character if it is preceded by a backslash. If a backslash character is
32596 immediately followed by a backslash character in *string1* or *string2*, the two
32597 backslash characters shall be counted as a single literal backslash character. The
32598 meaning of a backslash followed by any character that is not 'n', a backslash, or |
32599 the delimiter character is undefined.

[*0addr***]:***label* Do nothing. This command bears a *label* to which the **b** and **t** commands branch.

[*1addr***]=** Write the following to standard output:

"%d\n", <*current line number*>

[*0addr***]** Ignore this empty command.

[*0addr***]#** Ignore the '#' and the remainder of the line (treat them as a comment), with the single exception that if the first two characters in the script are "#n", the default output shall be suppressed; this shall be the equivalent of specifying **–n** on the command line.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Regular expressions match entire strings, not just individual lines, but a <newline> character is matched by '\n' in a *sed* RE; a <newline> character is not allowed by the general definition of regular expression in IEEE Std. 1003.1-200x. Also note that '\n' cannot be used to match a <newline> character at the end of an arbitrary input line; <newline> characters appear in the pattern space as a result of the **N** editing command.

EXAMPLES

This *sed* script simulates the BSD *cat* **–s** command, squeezing excess blank lines from standard input.

```
sed –n '
# Write non-empty lines.
/./ {
    p
    d
    }
# Write a single empty line, then look for more empty lines.
/^$/    p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/    {
    N
    s/.//
    b Empty
    }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
    p
'
```

32643 **RATIONALE**

32644 This volume of IEEE Std. 1003.1-200x requires implementations to support at least ten distinct
32645 *wfile*s, matching historical practice on many implementations. Implementations are encouraged
32646 to support more, but portable applications should not exceed this limit.

32647 The exit status codes specified here are different from those in System V. System V returns 2 for
32648 garbled *sed* commands, but returns zero with its usage message or if the input file could not be
32649 opened. The standard developers considered this to be a bug.

32650 The manner in which the **l** command writes non-printable characters was changed to avoid the
32651 historical backspace-overstrike method, and other requirements to achieve unambiguous output
32652 were added. See the RATIONALE for *ed* (on page 2546) for details of the format chosen, which is
32653 the same as that chosen for *sed*.

32654 This volume of IEEE Std. 1003.1-200x requires implementations to provide pattern and hold
32655 spaces of at least 8192 bytes, larger than the 4000 bytes spaces used by some historical
32656 implementations, but less than the 20480 bytes limit used in an early proposal. Implementations
32657 are encouraged to allocate dynamically larger pattern and hold spaces as needed.

32658 The requirements for acceptance of <blank> and <space> characters in command lines has been
32659 made more explicit than in early proposals to describe clearly the historical practice and to
32660 remove confusion about the phrase ''protect initial blanks [*sic*] and tabs from the stripping that
32661 is done on every script line'' that appears in much of the historical documentation of the *sed*
32662 utility description of text. (Not all implementations are known to have stripped <blank>
32663 characters from text lines, although they all have allowed leading <blank> characters preceding
32664 the address on a command line.)

32665 The treatment of `'#'` comments differs from the SVID which only allows a comment as the first
32666 line of the script, but matches BSD-derived implementations. The comment character is treated
32667 as a command, and it has the same properties in terms of being accepted with leading <blank>
32668 characters; the BSD implementation has historically supported this.

32669 Early proposals required that a *script_file* have at least one non-comment line. Some historical
32670 implementations have behaved in unexpected ways if this were not the case. The standard
32671 developers considered that this was incorrect behavior and that application developers should
32672 not have to avoid this feature. A correct implementation of this volume of IEEE Std. 1003.1-200x
32673 shall permit *script_file*s that consist only of comment lines.

32674 Early proposals indicated that if **–e** and **–f** options were intermixed, all **–e** options were
32675 processed before any **–f** options. This has been changed to process them in the order presented
32676 because it matches historical practice and is more intuitive.

32677 The treatment of the **p** flag to the **s** command differs between System V and BSD-based systems
32678 when the default output is suppressed. In the two examples:

32679 `echo a | sed    's/a/A/p'`
32680 `echo a | sed –n 's/a/A/p'`

32681 This volume of IEEE Std. 1003.1-200x, BSD, System V documentation, and the SVID indicate that
32682 the first example should write two lines with **A**, whereas the second should write one. Some
32683 System V systems write the **A** only once in both examples because the **p** flag is ignored if the **–n**
32684 option is not specified.

32685 This is a case of a diametrical difference between systems that could not be reconciled through
32686 the compromise of declaring the behavior to be unspecified. The SVID/BSD/System V
32687 documentation behavior was adopted for this volume of IEEE Std. 1003.1-200x because:

- No known documentation for any historic system describes the interaction between the **p** flag and the **–n** option.
- The selected behavior is more correct as there is no technical justification for any interaction between the **p** flag and the **–n** option. A relationship between **–n** and the **p** flag might imply that they are only used together, but this ignores valid scripts that interrupt the cyclical nature of the processing through the use of the **D**, **d**, **q**, or branching commands. Such scripts rely on the **p** suffix to write the pattern space because they do not make use of the default output at the ''bottom'' of the script.
- Because the **–n** option makes the **p** flag unnecessary, any interaction would only be useful if *sed* scripts were written to run both with and without the **–n** option. This is believed to be unlikely. It is even more unlikely that programmers have coded the **p** flag expecting it to be unnecessary. Because the interaction was not documented, the likelihood of a programmer discovering the interaction and depending on it is further decreased.
- Finally, scripts that break under the specified behavior produce too much output instead of too little, which is easier to diagnose and correct.

The form of the substitute command that uses the **n** suffix was limited to the first 512 matches in an early proposal. This limit has been removed because there is no reason an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/a/A/2047** should be able to substitute the 2 047th occurrence of **a** on a line.

The **b**, **t**, and **:** commands are documented to ignore leading white space, but no mention is made of trailing white space. Historical implementations of *sed* assigned different locations to the labels `'x'` and `"x "`. This is not useful, and leads to subtle programming errors, but it is historical practice, and changing it could theoretically break working scripts. Implementors are encouraged to provide warning messages about labels that are never used or jumps to labels that do not exist.

Historically, the *sed* **!** and **}** editing commands did not permit multiple commands on a single line using a semicolon as a command delimiter. Implementations are permitted, but not required, to support this extension.

FUTURE DIRECTIONS

None.

awk, *ed*, *grep*

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Issue 5

FUTURE DIRECTIONS section added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Implementations are required to support at least ten *wfile* arguments in an editing command.

The EXTENDED DESCRIPTION is changed to align with the IEEE P1003.2b draft standard.

32731 **NAME**

32732 sh — shell, the standard command language interpreter

32733 **SYNOPSIS**

32734 `sh [`–abCefhimnuvx`][`–o *option*`][`+abCefhmnuvx`][`+o *option*`]` |
32735 `[`*command_file* `[`*argument*`...]]` |

32736 `sh –c[`–abCefhimnuvx`][`–o *option*`][`+abCefhimnuvx`][`+o *option*`]`*command_string* |
32737 `[`*command_name* `[`*argument*`...]]` /

32738 `sh –s[`–abCefhimnuvx`][`–o *option*`][`+abCefhimnuvx`][`+o *option*`][`*argument*`]` |

32739 **DESCRIPTION** |

32740 The *sh* utility is a command language interpreter that shall execute commands read from a
32741 command line string, the standard input, or a specified file. The application shall ensure that the
32742 commands to be executed are expressed in the language described in Chapter 2 (on page 2235).

32743 Path name expansion does not fail due to the size of a file. |

32744 ***Notes to Reviewers*** |

32745 *This section with side shading will not appear in the final copy. - Ed.* |

32746 D3, XCU, ERN 215: Text here is unclear. There is nothing under the stat command that permits it |
32747 to fail on a very large file. |

32748 Shell input and output redirections have an implementation-defined offset maximum that is |
32749 established in the open file description. |

32750 **OPTIONS**

32751 The *sh* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, |
32752 Utility Syntax Guidelines, with an extension for support of a leading plus sign (`'+'`) as noted |
32753 below. |

32754 The **–a**, **–b**, **–C**, **–e**, **–f**, **–m**, **–n**, **–o** *option*, **–u**, **–v**, and **–x** options are described as part of the *set*
32755 utility in Section 2.15 (on page 2276). The option letters derived from the *set* special built-in shall |
32756 also be accepted with a leading plus sign (`'+'`) instead of a leading hyphen (meaning the reverse
32757 case of the option as described in this volume of IEEE Std. 1003.1-200x). |

32758 The following additional options shall be supported:

32759 **–c** Read commands from the *command_string* operand. Set the value of special
32760 parameter 0 (see Section 2.5.2 (on page 2241)) from the value of the *command_name*
32761 operand and the positional parameters ($1, $2, and so on) in sequence from the
32762 remaining *argument* operands. No commands shall be read from the standard
32763 input.

32764 **–i** Specify that the shell is *interactive*; see below. An implementation may treat
32765 specifying the **–i** option as an error if the real user ID of the calling process does
32766 not equal the effective user ID or if the real group ID does not equal the effective
32767 group ID.

32768 **–s** Read commands from the standard input.

32769 If there are no operands and the **–c** option is not specified, the **–s** option shall be assumed.

32770 If the **–i** option is present, or if there are no operands and the shell's standard input and standard
32771 error are attached to a terminal, the shell is considered to be *interactive*.

OPERANDS

The following operands shall be supported:

– A single hyphen is treated as the first operand and then ignored. If both '–' and "—" are given as arguments, or if other operands precede the single hyphen, the results are undefined.

argument The positional parameters ($1, $2, and so on) shall be set to *arguments*, if any.

command_file The path name of a file containing commands. If the path name contains one or more slash characters, the implementation attempts to read that file; the file need not be executable. If the path name does not contain a slash character:

- The implementation shall attempt to read that file from the current working directory; the file need not be executable.
- If the file is not in the current working directory, the implementation may perform a search for an executable file using the value of *PATH*, as described in Section 2.9.1.1 (on page 2257).

Special parameter 0 (see Section 2.5.2 (on page 2241)) shall be set to the value of *command_file*. If *sh* is called using a synopsis form that omits *command_file*, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a path name used to execute the *sh* utility.

command_name
A string assigned to special parameter 0 when executing the commands in *command_string*. If *command_name* is not specified, special parameter 0 shall be set to the value of the first argument passed to *sh* from its parent (for example, *argv*[0] for a C program), which is normally a path name used to execute the *sh* utility.

command_string
A string that shall be interpreted by the shell as one or more commands, as if the string were the argument to the *system*( ) function defined in the System Interfaces volume of IEEE Std. 1003.1-200x. If the *command_string* operand is an empty string, *sh* shall exit with a zero exit status.

STDIN

The standard input shall be used only if one of the following is true:

- The **–s** option is specified.
- The **–c** option is not specified and no operands are specified.
- The script executes one or more commands that require input from standard input (such as a *read* command that does not redirect its input).

See the INPUT FILES section.

When the shell is using standard input and it invokes a command that also uses standard input, the shell shall ensure that the standard input file pointer points directly after the command it has read when the command begins execution. It shall not read ahead in such a manner that any characters intended to be read by the invoked command are consumed by the shell (whether interpreted by the shell or not) or that characters that are not read by the invoked command are not seen by the shell. When the command expecting to read standard input is started asynchronously by an interactive shell, it is unspecified whether characters are read by the command or interpreted by the shell.

If the standard input to *sh* is a FIFO or terminal device and is set to non-blocking reads, then *sh* shall enable blocking reads on standard input. This shall remain in effect when the command completes.

INPUT FILES

The input file shall be a text file, except that line lengths shall be unlimited. If the input file is empty or consists solely of blank lines or comments, or both, *sh* shall exit with a zero exit status.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *sh*:

ENV This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2 (on page 2245)) by the shell, and the resulting value shall be used as a path name of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of *ENV* is not an absolute path name, the results are unspecified. *ENV* shall be ignored if the real and effective user IDs or real and effective group IDs of the process are different.

FCEDIT This variable, when expanded by the shell, determines the default value for the **−e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be used as the editor. This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

HISTFILE Determine a path name naming a command history file. If the *HISTFILE* variable is not set, the shell may attempt to access or create a file **.sh_history** in the directory referred to by the *HOME* environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history ''file'' in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when *fc* or *sh* first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the *ENV* variable, or implementation-defined system start-up files. (The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the user's settings of *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file, unless the *set* **−o** *nolog* option is set. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user gets a chance to influence its characteristics.) In some historical shells, the history file is initialized just after the *ENV* file has been processed. Therefore, it is implementation-defined whether changes made to *HISTFILE* after the history file has been initialized are effective. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set *HISTFILE*; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file. This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

HISTSIZE Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default

greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE* after the history file has been initialized are effective.

HOME Determine the path name of the user's home directory. The contents of *HOME* are used in Tilde Expansion as described in Section 2.6.1 (on page 2244). This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

IFS *Input field separators*: a string treated as a list of characters that shall be used for field splitting and to split lines into words with the *read* command. See Section 2.6.5 (on page 2249). If *IFS* is not set, the shell shall behave as if the value of *IFS* were the <space>, <tab>, and <newline> characters. Implementations may ignore the value of *IFS* in the environment at the time *sh* is invoked, treating *IFS* as if it were not set.

LANG Provide a default value for the internationalization variables that are unset or null. If *LANG* is unset or null, the corresponding value from the implementation-defined default locale shall be used. If any of the internationalization variables contains an invalid setting, the utility shall behave as if none of the variables had been defined.

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the behavior of range expressions, equivalence classes and multi-character collating elements within pattern matching.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), which characters are defined as letters (character class **alpha**), and the behavior of character classes within pattern matching.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

MAIL Determine a path name of the user's mailbox file for purposes of incoming mail notification. If this variable is set, the shell shall inform the user if the file named by the variable is created or if its modification time has changed. Informing the user shall be accomplished by writing a string of unspecified format to standard error prior to the writing of the next primary prompt string after the completion of an interval defined by the *MAILCHECK* variable. The user shall be informed only if *MAIL* is set and *MAILPATH* is not set. This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

MAILCHECK
Establish a decimal integer value that specifies how often (in seconds) the shell shall check for the arrival of mail in the files specified by the *MAILPATH* or *MAIL* variables. The default value shall be 600 seconds. If set to zero, the shell shall check before issuing each primary prompt. This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

MAILPATH Provide a list of path names and optional messages separated by colons. If this variable is set, the shell shall inform the user if any of the files named by the variable are created or if any of their modification times change. (See the preceding entry for *MAIL* for descriptions of mail arrival and user informing.) Each path name can be followed by '%' and a string that shall be subjected to parameter expansion and written to standard error when the modification time changes. If a '%' character in the path name is preceded by a backslash, it shall be treated as a literal '%' in the path name. The default message is unspecified.

The *MAILPATH* environment variable takes precedence over the *MAIL* variable. This volume of IEEE Std. 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Establish a string formatted as described in the Base Definitions volume of IEEE Std. 1003.1-200x, Chapter 8, Environment Variables, used to effect command interpretation; see Section 2.9.1.1 (on page 2257).

PWD This variable shall represent an absolute path name of the current working directory. Assignments to this variable may be ignored unless the value is an absolute path name of the current working directory and there are no file name components of dot or dot-dot.

ASYNCHRONOUS EVENTS

Default.

STDOUT

See the STDERR section.

STDERR

Except as otherwise stated (by the descriptions of any invoked utilities or in interactive mode), standard error is used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

See Chapter 2. The following additional capabilities are supported on systems supporting the User Portability Utilities option.

Command History List

When the *sh* utility is being used interactively, it shall maintain a list of commands previously entered from the terminal in the file named by the *HISTFILE* environment variable. The type, size, and internal format of this file are unspecified. Multiple *sh* processes can share access to the file for a user, if file access permissions allow this; see the description of the *HISTFILE* environment variable.

Command Line Editing

When *sh* is being used interactively from a terminal, the current command and the command history (see *fc* (on page 2646)) can be edited using *vi*-mode command line editing. This mode uses commands, described below, similar to a subset of those described in the *vi* utility. Implementations may offer other command line editing modes corresponding to other editing utilities.

The command *set* **−o** *vi* shall enable *vi*-mode editing and place *sh* into *vi* insert mode (see **Command Line Editing (vi-mode)**). This command also shall disable any other editing mode that the implementation may provide. The command *set* **+o** *vi* disables *vi*-mode editing.

Certain block-mode terminals may be unable to support shell command line editing. If a terminal is unable to provide either edit mode, it need not be possible to *set* **−o** *vi* when using the shell on this terminal.

In the following sections, the characters *erase*, *interrupt*, *kill*, and *end-of-file* are those set by the *stty* utility.

Command Line Editing (vi-mode)

With *vi*-mode enabled, *sh* can be switched between insert mode and command mode.

When in insert mode, an entered character shall be inserted into the command line, except as noted in **vi Line Editing Insert Mode**. Upon entering *sh* and after termination of the previous command, *sh* shall be in insert mode.

Typing an escape character shall switch *sh* into command mode (see **vi Line Editing Command Mode** (on page 3066)). In command mode, an entered character shall either invoke a defined operation, is used as part of a multi-character operation, or is treated as an error. A character that is not recognized as part of an editing command shall terminate any specific editing command and shall alert the terminal. Typing the *interrupt* character in command mode shall cause *sh* to terminate command line editing on the current command line, reissue the prompt on the next line of the terminal, and reset the command history (see *fc* (on page 2646)) so that the most recently executed command is the previous command (that is, the command that was being edited when it was interrupted is not reentered into the history).

In the following sections, the phrase ‘‘move the cursor to the beginning of the word’’ shall mean ‘‘move the cursor to the first character of the current word’’ and the phrase ‘‘move the cursor to the end of the word’’ shall mean ‘‘move the cursor to the last character of the current word’’. The phrase ‘‘beginning of the command line’’ indicates the point between the end of the prompt string issued by the shell (or the beginning of the terminal line, if there is no prompt string) and the first character of the command text.

vi Line Editing Insert Mode

While in insert mode, any character typed shall be inserted in the current command line, unless it is from the following set.

<newline> Execute the current command line being edited.

erase Delete the character previous to the current cursor position and move the current cursor position back one character. In insert mode, characters shall be erased from both the screen and the buffer when backspacing.

interrupt Terminate command line editing with the same effects as described for interrupting command mode; see **Command Line Editing (vi-mode)**.

kill Clear all the characters from the input line.

<control>-V Insert the next character input, even if the character is otherwise a special insert mode character.

<control>-W Delete the characters from the one preceding the cursor to the preceding word boundary. The word boundary in this case is the closer to the cursor of either the beginning of the line or a character that is in neither the **blank** nor **punct** character classification of the current locale.

end-of-file Interpreted as the end of input in *sh*. This interpretation shall occur only at the beginning of an input line. If *end-of-file* is entered other than at the beginning of the line, the results are unspecified.

<ESC> Place *sh* into command mode.

vi Line Editing Command Mode

In command mode for the command line editing feature, decimal digits not beginning with 0 that precede a command letter shall be remembered. Some commands use these decimal digits as a count number that affects the operation.

The term *motion command* represents one of the commands:

```
<space>  0  b  F  l  W  ^  $  ;  E  f  T  w  |  ,  B  e  h  t
```

Any command that modifies the current line shall cause a copy of the current line to be made at the end of the command history, the current line shall become that copy, and the edit is performed on that copy.

Any command that is preceded by *count* shall take a count (the numeric value of any preceding decimal digits). Unless otherwise noted, this count shall cause the specified operation to repeat by the number of times specified by the count. Also unless otherwise noted, a *count* that is out of range is considered an error condition and shall alert the terminal, but neither the cursor position, nor the command line, shall change.

The terms *word* and *bigword* are used as defined in the *vi* description. The term *save buffer* corresponds to the term *unnamed buffer* in *vi*.

The following commands shall be recognized in command mode:

<newline> Execute the current command line being edited.

<control>-L Redraw the current command line. Position the cursor at the same location on the new command line.

Insert the character `'#'` at the beginning of the current command line and treat the current command line as a comment. This line shall be entered into the command history; see *fc* (on page 2646).

= Display the possible shell word expansions (see Section 2.6 (on page 2244)) of the bigword at the current command line position. These expansions shall be displayed on subsequent terminal lines. If the bigword contains none of the characters `'?'`, `'*'`, or `'['`, an asterisk (`'*'`) shall be implicitly assumed at the end. If any directories are matched, these expansions shall have a `'/'` character appended. After the expansion, the line shall be redrawn, the cursor is repositioned at the current cursor position, and *sh* shall be placed in command mode.

**** Perform path name expansion (see Section 2.6.6 (on page 2249)) on the current bigword, up to the largest set of characters that can be matched uniquely. If the

bigword contains none of the characters '?', '*', or '[', an asterisk ('*') shall be implicitly assumed at the end. This maximal expansion then shall replace the original bigword in the command line, and the cursor shall be placed after this expansion. If the resulting bigword completely and uniquely matches a directory, a '/' character shall be inserted directly after the bigword. If some other file is completely matched, a single <space> character shall be inserted after the bigword. After this operation, *sh* shall be placed in insert mode.

***** Perform path name expansion on the current bigword and insert all expansions into the command to replace the current bigword, with each expansion separated by a single <space> character. If at the end of the line, the current cursor position shall be moved to the first column position following the expansions and *sh* shall be placed in insert mode. Otherwise, the current cursor position shall be the last column position of the first character after the expansions and *sh* shall be placed in insert mode. If the current bigword contains none of the characters '?', '*', or '[', before the operation, an asterisk shall be implicitly assumed at the end.

@*letter* Insert the value of the alias named *_letter*. The symbol *letter* represents a single alphabetic character from the portable character set; implementations may support additional characters as an extension. If the alias *_letter* contains other editing commands, these commands shall be performed as part of the insertion. If no alias *_letter* is enabled, this command shall have no effect.

[*count***]~** Convert, if the current character is a lowercase letter, to the equivalent uppercase letter and *vice versa*, as prescribed by the current locale. The current cursor position then shall be advanced by one character. If the cursor was positioned on the last character of the line, the case conversion shall occur, but the cursor shall not advance. If the '~' command is preceded by a *count*, that number of characters shall be converted, and the cursor shall be advanced to the character position after the last character converted. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***].** Repeat the most recent non-motion command, even if it was executed on an earlier command line. If the previous command was preceded by a *count*, and no count is given on the '.' command, the count from the previous command shall be included as part of the repeated command. If the '.' command is preceded by a *count*, this shall override any *count* argument to the previous command. The *count* specified in the '.' command shall become the count for subsequent '.' commands issued without a count.

[*number***]v** Invoke the *vi* editor to edit the current command line in a temporary file. When the editor exits, the commands in the temporary file shall be executed. If a *number* is prefixed to the command, it specifies the command number in the command history to be edited, rather than the current command line.

[*count***]l** (ell)
[*count***]**<space>
Move the current cursor position to the next character position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]h** Move the current cursor position to the *count*th (default 1) previous character position. If the cursor was positioned on the first character of the line, the terminal

shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this shall not be considered an error; the cursor shall move to the first character on the line.

[*count***]w** Move to the start of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]W** Move to the start of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]e** Move to the end of the current word. If at the end of a word, move to the end of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]E** Move to the end of the current bigword. If at the end of a bigword, move to the end of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the *count* is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line.

[*count***]b** Move to the beginning of the current word. If at the beginning of a word, move to the beginning of the previous word. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of words preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.

[*count***]B** Move to the beginning of the current bigword. If at the beginning of a bigword, move to the beginning of the previous bigword. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of bigwords preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line.

^ Move the current cursor position to the first character on the input line that is not a <blank> character.

$ Move to the last character position on the current command line.

0 (Zero.) Move to the first character position on the current command line.

[*count***] |** Move to the *count*th character position on the current command line. If no number is specified, move to the first position. The first character position shall be numbered 1. If the count is larger than the number of characters on the line, this shall not be considered an error; the cursor shall be placed on the last character on the line.

[*count***]f***c* Move to the first occurrence of the character `'c'` that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character `'c'`

does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]F***c* Move to the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'` does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]t***c* Move to the character before the first occurrence of the character `'c'` that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character `'c'` does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***]T***c* Move to the character after the first occurrence of the character `'c'` that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character `'c'` does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved.

[*count***];** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. Errors are those described for the repeated command.

[*count***],** Repeat the most recent **f**, **F**, **t**, or **T** command. Any number argument on that previous command shall be ignored. However, reverse the direction of that command.

a Enter insert mode after the current cursor position. Characters that are entered shall be inserted before the next character.

A Enter insert mode after the end of the current command line.

i Enter insert mode at the current cursor position. Characters that are entered are inserted before the current character.

I Enter insert mode at the beginning of the current command line.

R Enter insert mode, replacing characters from the command line beginning at the current cursor position.

[*count***]c***motion*

Delete the characters between the current cursor position and the cursor position that would result from the specified *motion* command. Then enter insert mode before the first character following any deleted characters. If *count* is specified, it shall be applied to the motion command. A *count* shall be ignored for the following motion commands:

```
0     ^     $     c
```

If the *motion* command is the character `'c'`, the current command line shall be cleared and insert mode shall be entered. If the *motion* command would move the current cursor position toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command would move the current cursor position toward the end of the command line, the character under the current cursor position shall be deleted. If the *count* is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor,

this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted and insert mode shall be entered. If the motion command is invalid, the terminal shall be alerted, the cursor shall not be moved, and no text shall be deleted.

C Delete from the current character to the end of the line and enter insert mode at the new end-of-line.

S Clear the entire current command line and enter insert mode.

[*count***]r***c* Replace the current character with the character `'c'`. With a number *count*, replace the current and the following *count*−1 characters. After this command, the current cursor position shall be on the last character that was changed. If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all of the remaining characters shall be changed.

[*count***]_** Append a <space> character after the current character position and then append the last bigword in the previous input line after the <space> character. Then enter insert mode after the last character just appended. With a number *count*, append the *count*th bigword in the previous line.

[*count***]x** Delete the character at the current cursor position and place the deleted characters in the save buffer. If the cursor was positioned on the last character of the line, the character shall be deleted and the cursor position shall be moved to the previous character (the new last character). If the *count* is larger than the number of characters after the cursor, this shall not be considered an error; all the characters from the cursor to the end of the line shall be deleted.

[*count***]X** Delete the character before the current cursor position and place the deleted characters in the save buffer. The character under the current cursor position shall not change. If the cursor was positioned on the first character of the line, the terminal shall be alerted, and the **X** command shall have no effect. If the line contained a single character, the **X** command shall have no effect. If the line contained no characters, the terminal shall be alerted and the cursor shall not be moved. If the *count* is larger than the number of characters before the cursor, this shall not be considered an error; all the characters from before the cursor to the beginning of the line shall be deleted.

[*count***]d***motion*

Delete the characters between the current cursor position and the character position that would result from the *motion* command. A number *count* repeats the *motion* command *count* times. If the *motion* command would move toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the *motion* command is **d**, the entire current command line shall be cleared. If the *count* is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted. The deleted characters shall be placed in the save buffer.

D Delete all characters from the current cursor position to the end of the line. The deleted characters shall be placed in the save buffer.

[*count***]y***motion*

Yank (that is, copy) the characters from the current cursor position to the position resulting from the *motion* command into a save buffer. A number *count* shall be applied to the *motion* command. If the *motion* command would move toward the

33226 beginning of the command line, the character under the current cursor position
33227 shall not be included in the set of yanked characters. If the *motion* command is **y**,
33228 the entire current command line shall be yanked into the save buffer. The current
33229 cursor position shall be unchanged. If the *count* is larger than the number of
33230 characters between the current cursor position and the end of the command line
33231 toward which the motion command would move the cursor, this shall not be
33232 considered an error; all of the remaining characters in the aforementioned range
33233 shall be yanked.

33234 **Y** Yank the characters from the current cursor position to the end of the line into the
33235 save buffer. The current character position shall be unchanged.

33236 **[***count***]p** Put a copy of the current contents of the save buffer after the current cursor
33237 position. The current cursor position shall be advanced to the last character put
33238 from the save buffer. A *count* shall indicate how many copies of the save buffer
33239 shall be put.

33240 **[***count***]P** Put a copy of the current contents of the save buffer before the current cursor
33241 position. The current cursor position shall be moved to the last character put from
33242 the save buffer. A *count* shall indicate how many copies of the save buffer shall be
33243 put.

33244 **u** Undo the last command that modified the text of the current command line.

33245 **U** Undo all changes made to the current command line since first entering command
33246 mode on the line.

33247 **[***count***]k**
33248 **[***count***]**– Replace the current command line with the previous command line in the shell
33249 command history. The cursor shall be positioned on the first character of the new
33250 command. A count preceding the command shall have the same effect as
33251 executing the command *count* times. If a **k** or – command retreats past the
33252 maximum number of commands in effect for this shell (affected by the *HISTSIZE*
33253 environment variable), the terminal shall be alerted and the command shall have
33254 no effect.

33255 **[***count***]j**
33256 **[***count***]+** Replace the current command line with the next command line in the shell
33257 command history. The cursor shall be positioned on the first character of the new
33258 command. The command history position shall be remembered, and any **k** or –
33259 command, or **j** or **+** command, shall decrement or increment that position and then
33260 shall fetch the line at the new position. If a **j** or **+** command advances past the most
33261 recent line in the history, the current command line shall be restored to the
33262 contents before the first **k** or –.

33263 **[***number***]G** Replace the current command line with the contents of the oldest command line
33264 stored in the shell command history. With a number *number*, replace the current
33265 command line with the contents of command *number* in the history.

33266 **/***string*<newline>
33267 Move backward through the command history, searching for the specified *string*,
33268 beginning with the previous command line. If it is not found, the current
33269 command line shall be unchanged. If it is found in a previous line, this command
33270 shall behave equivalently to a set of **k** commands to reach that line. If *string* begins
33271 with `'^'`, the characters after the `'^'` shall be matched only at the beginning of a
33272 line.

?*string*<newline>
: Move forward through the command history, searching for the specified string. If it is not found, the current command line shall be unchanged. If the string is found in the current command line, the current cursor position shall be moved to the beginning of that string. If it is found in the history, this command shall behave equivalently to a set of **j** commands to reach that line. If *string* begins with `'^'`, the characters after the `'^'` shall be matched only at the beginning of a line.

n
: Repeat the most recent **/** or **?** command.

N
: Repeat the most recent **/** or **?** command, reversing the direction of the search.

EXIT STATUS

The following exit values shall be returned:

0
: The script to be executed consisted solely of zero or more blank lines or comments, or both.

1-125
: A non-interactive shell detected a syntax, redirection or variable assignment error.

127
: A specified *command_file* could not be found by a non-interactive shell.

Otherwise, the shell shall return the exit status of the last command it invoked or attempted to invoke (see also the *exit* utility in Section 2.15 (on page 2276)).

CONSEQUENCES OF ERRORS

See Section 2.8.1 (on page 2255).

APPLICATION USAGE

Standard input and standard error are the files that determine whether a shell is interactive when **–i** is not specified. For example:

```
sh > file
```

and:

```
sh 2> file
```

create interactive and non-interactive shells, respectively. Although both accept terminal input, the results of error conditions are different, as described in Section 2.8.1 (on page 2255); in the second example a redirection error encountered by a special built-in utility aborts the shell.

A portable application must protect its first operand, if it starts with a plus sign, by preceding it with the "––" argument that denotes the end of the options.

Applications should note that the standard *PATH* to the shell cannot be assumed to be either **/bin/sh** or **/usr/bin/sh**, and should be determined by interrogation of the *PATH* returned by *getconf PATH*, ensuring that the returned path name is an absolute path name and not a shell built in.

For example, to determine the location of the standard *sh* utility:

```
command –v sh
```

On some systems this might return:

```
/usr/xpg4/bin/sh
```

Furthermore, on systems that support executable scripts (the "#!" construct), it is recommended that applications using executable scripts install them using *getconf* **–v** to determine the shell path name and update the "#!" script appropriately as it is being installed (for example, with *sed*). For example:

```
#
# Installation time script to install correct POSIX shell path name
#
# Get list of paths to check
#
Sifs=$IFS
IFS=:
set $(getconf PATH)
IFS=$Sifs
#
# Check each path for 'sh'
#
for i in $@
do
    if [ -f ${i}/sh ];
    then
        Pshell=${i}/sh
    fi
done
#
# This is the list of scripts to update. They should be of the
# form '${name}.source' and will be transformed to '${name}'.
# Each script should begin:
#
# !INSTALLSHELLPATH -p
#
scripts="a b c"
#
# Transform each script
#
for i in ${scripts}
do
    sed -e "s|INSTALLSHELLPATH|${Pshell}|" < ${i}.source > ${i}
done
```

EXAMPLES

1. Execute a shell command from a string:

   ```
   sh -c "cat myfile"
   ```

2. Execute a shell script from a file in the current directory:

   ```
   sh my_shell_cmds
   ```

RATIONALE

The *sh* utility and the *set* special built-in utility share a common set of options.

The KornShell ignores the contents of *IFS* upon entry to the script. A conforming application cannot rely on importing *IFS*. One justification for this, beyond security considerations, is to assist possible future shell compilers. Allowing *IFS* to be imported from the environment prevents many optimizations that might otherwise be performed via dataflow analysis of the script itself.

The text in the STDIN section about non-blocking reads concerns an instance of *sh* that has been invoked, probably by a C-language program, with standard input that has been opened using

the O_NONBLOCK flag; see *open*( ) in the System Interfaces volume of IEEE Std. 1003.1-200x. If the shell did not reset this flag, it would immediately terminate because no input data would be available yet and that would be considered the same as end-of-file.

The options associated with a *restricted shell* (command name *rsh* and the **–r** option) were excluded because the standard developers considered that the implied level of security could not be achieved and they did not want to raise false expectations.

On systems that support set-user-ID scripts, a historical trapdoor has been to link a script to the name **–i**. When it is called by a sequence such as

```
sh –
```

or by:

```
#! usr/bin/sh –
```

the historical systems have assumed that no option letters follow. Thus, this volume of IEEE Std. 1003.1-200x allows the single hyphen to mark the end of the options, in addition to the use of the regular "––" argument, because it was considered that the older practice was so pervasive. An alternative approach is taken by the KornShell, where real and effective user/group IDs must match for an interactive shell; this behavior is specifically allowed by this volume of IEEE Std. 1003.1-200x.

Note: There are other problems with set-user-ID scripts that the two approaches described here do not resolve.

The default messages for the various *MAIL*-related messages are unspecified because they vary across implementations. Typical messages are:

```
"you have mail\n"
```

or:

```
"you have new mail\n"
```

It is important that the descriptions of command line editing refer to the same shell as that in IEEE Std. 1003.1-200x so that interactive users can also be application programmers without having to deal with programmatic differences in their two environments. It is also essential that the utility name *sh* be specified because this explicit utility name is too firmly rooted in historical practice of application programs for it to change.

Consideration was given to mandating a diagnostic message when attempting to set *vi*-mode on terminals that do not support command line editing. However, it is not historical practice for the shell to be cognizant of all terminal types and thus be able to detect inappropriate terminals in all cases. Implementations are encouraged to supply diagnostics in this case whenever possible, rather than leaving the user in a state where editing commands work incorrectly.

In early proposals, the KornShell-derived *emacs* mode of command line editing was included, even though the *emacs* editor itself was not. The community of *emacs* proponents was adamant that the full *emacs* editor not be included in this volume of IEEE Std. 1003.1-200x because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to this volume of IEEE Std. 1003.1-200x, but lacking the extensibility required by the community. The author of the original *emacs* program also expressed his desire to omit the program. Furthermore, there were a number of historical systems that did not include *emacs*, or included it without supporting it, but there were very few that did not include and support *vi*. The shell *emacs* command line editing mode was finally omitted from this volume of IEEE Std. 1003.1-200x because it became apparent that the KornShell version and the editor being distributed with the GNU system had diverged in some

respects. The author of *emacs* requested that the POSIX *emacs* mode either be deleted or have a significant number of unspecified conditions. Although the KornShell author agreed to consider changes to bring the shell into alignment, the standard developers decided to defer specification at this time, rather than attempting to agree on a specific subset of *emacs* late within the development of this volume of IEEE Std. 1003.1-200x. It is assumed that the *emacs* and KornShell developers will converge on a definition acceptable to both groups, and this may be used as a model for a future version of this volume of IEEE Std. 1003.1-200x. In the interim, implementations are free to offer additional command line editing modes based on the exact models of editors their users are most comfortable with.

Early proposals had the following list entry in **vi Line Editing Insert Mode** (on page 3065):

\ If followed by the *erase* or *kill* character, that character shall be inserted into the input line. Otherwise, the backslash itself shall be inserted into the input line.

However, this is not actually a feature of *sh* command line editing insert mode, but one of some historical terminal line drivers. Some conforming implementations continue to do this when the *stty* **iexten** flag is set.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 4

Aligned with the ISO / IEC 9945-2: 1993 standard.

Description of the shell command language and special built-ins moved to Chapter 2 (on page 2235).

Issue 5

FUTURE DIRECTIONS section added.

Text is added to the DESCRIPTION for the Large File Summit proposal.

Issue 6

The Open Group corrigenda item U029 / 2 has been applied, correcting the second SYNOPSIS.

The Open Group corrigenda item U027 / 3 has been applied, correcting a typographical error.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The option letters derived from the set special built-in are also accepted with a leading plus sign (′+′).
- Large file extensions are added:
  - — Path name expansion does not fail due to the size of a file.
  - — Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

In the ENVIRONMENT VARIABLES section, the text ‘‘user’s home directory’’ is updated to ‘‘directory referred to by the *HOME* environment variable’’.

Descriptions for the *ENV* and *PWD* environment variables are included to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term ‘‘must’’ for application requirements.

33453 **NAME**

33454 sleep — suspend execution for an interval

33455 **SYNOPSIS**

33456 `sleep` *`time`*

33457 **DESCRIPTION**

33458 The *sleep* utility shall suspend execution for at least the integral number of seconds specified by
33459 the *time* operand.

33460 **OPTIONS**

33461 None.

33462 **OPERANDS**

33463 The following operand shall be supported:

33464 *time* A non-negative decimal integer specifying the number of seconds for which to
33465 suspend execution.

33466 **STDIN**

33467 Not used.

33468 **INPUT FILES**

33469 None.

33470 **ENVIRONMENT VARIABLES**

33471 The following environment variables shall affect the execution of *sleep*:

33472 *LANG* Provide a default value for the internationalization variables that are unset or null.
33473 If *LANG* is unset or null, the corresponding value from the implementation-
33474 defined default locale shall be used. If any of the internationalization variables
33475 contains an invalid setting, the utility shall behave as if none of the variables had
33476 been defined.

33477 *LC_ALL* If set to a non-empty string value, override the values of all the other
33478 internationalization variables.

33479 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
33480 characters (for example, single-byte as opposed to multi-byte characters in
33481 arguments).

33482 *LC_MESSAGES*

33483 Determine the locale that should be used to affect the format and contents of
33484 diagnostic messages written to standard error.

33485 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

33486 **ASYNCHRONOUS EVENTS**

33487 If the *sleep* utility receives a SIGALRM signal, one of the following actions shall be taken:

33488 1. Terminate normally with a zero exit status.

33489 2. Effectively ignore the signal.

33490 3. Provide the default behavior for signals described in the ASYNCHRONOUS EVENTS
33491 section of Section 1.11 (on page 2224). This could include terminating with a non-zero exit
33492 status.

33493 The *sleep* utility shall take the standard action for all other signals.

STDOUT

Not used.

STDERR

Used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The execution was successfully suspended for at least *time* seconds, or a SIGALRM signal was received. See the ASYNCHRONOUS EVENTS section.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The *sleep* utility can be used to execute a command after a certain amount of time, as in:

```
(sleep 105; command) &
```

or to execute a command every so often, as in:

```
while true
do
    command
    sleep 37
done
```

RATIONALE

The exit status is allowed to be zero when *sleep* is interrupted by the SIGALRM signal because most implementations of this utility rely on the arrival of that signal to notify them that the requested finishing time has been successfully attained. Such implementations thus do not distinguish this situation from the successful completion case. Other implementations are allowed to catch the signal and go back to sleep until the requested time expires or to provide the normal signal termination procedures.

As with all other utilities that take integral operands and do not specify subranges of allowed values, *sleep* is required by this volume of IEEE Std. 1003.1-200x to deal with *time* requests of up to 2 147 483 647 seconds. This may mean that some implementations have to make multiple calls to the delay mechanism of the underlying operating system if its argument range is less than this.

FUTURE DIRECTIONS

None.

33536 **CHANGE HISTORY**

33537 First released in Issue 2.

33538 **Issue 4**

33539 Aligned with the ISO / IEC 9945-2: 1993 standard.

NAME

sort — sort, merge, or sequence check text files

SYNOPSIS

```
sort [–m][–o output][–bdfinru][–t char][–k keydef]... [file...]
sort –c [–bdfinru][–t char][–k keydef]... file
```

DESCRIPTION

The *sort* utility shall perform one of the following functions:

1. Sort lines of all the named files together and write the result to the specified output.
2. Merge lines of all the named (presorted) files together and write the result to the specified output.
3. Check that a single input file is correctly presorted.

Comparisons shall be based on one or more sort keys extracted from each line of input (or, if no sort keys are specified, the entire line up to, but not including, the terminating <newline> character), and shall be performed using the collating sequence of the current locale.

OPTIONS

The *sort* utility shall conform to the Base Definitions volume of IEEE Std. 1003.1-200x, Section 12.2, Utility Syntax Guidelines, and the **–k** *keydef* option should follow the **–b**, **–d**, **–f**, **–i**, **–n**, and **–r** options.

The following options shall be supported:

–c Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. No output shall be produced; only the exit code shall be affected.

–m Merge only; the input file shall be assumed to be already sorted.

–o *output* Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input *file*s.

–u Unique: suppress all but one in each set of lines having equal keys. If used with the **–c** option, check that there are no lines with duplicate keys, in addition to checking that the input file is sorted.

The following options shall override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules shall be applied globally to all sort keys. When attached to a specific key (see **–k**), the specified ordering options shall override all global ordering options for that key.

–d Specify that only <blank> characters and alphanumeric characters, according to the current setting of *LC_CTYPE*, shall be significant in comparisons. The behavior is undefined for a sort key to which **–i** or **–n** also applies.

–f Consider all lowercase characters that have uppercase equivalents, according to the current setting of *LC_CTYPE*, to be the uppercase equivalent for the purposes of comparison.

–i Ignore all characters that are non-printable, according to the current setting of *LC_CTYPE*.

–n Restrict the sort key to an initial numeric string, consisting of optional <blank> characters, optional minus sign, and zero or more digits with an optional radix character and thousands separators (as defined in the current locale), which shall

be sorted by arithmetic value. An empty digit string shall be treated as zero. Leading zeros and signs on zeros shall not affect ordering.

–r Reverse the sense of comparisons.

The treatment of field separators can be altered using the options:

–b Ignore leading <blank> characters when determining the starting and ending positions of a restricted sort key. If the **–b** option is specified before the first **–k** option, it shall be applied to all **–k** options. Otherwise, the **–b** option can be attached independently to each **–k** *field_start* or *field_end* option-argument (see below).

–t *char* Use *char* as the field separator character; *char* shall not be considered to be part of a field (although it can be included in a sort key). Each occurrence of *char* shall be significant (for example, <*char*><*char*> delimits an empty field). If **–t** is not specified, <blank> characters shall be used as default field separators; each maximal non-empty sequence of <blank> characters that follows a non-<blank> character shall be a field separator.

Sort keys can be specified using the options:

–k *keydef* The *keydef* argument is a restricted sort key field definition. The format of this definition is:

field_start`[`*type*`][,`*field_end*`[`*type*`]]`
